

Intel® Xeon™ Processor with 512-KB L2 Cache at 1.80 GHz to 3 GHz

Datasheet

Product Features

- Available at 1.80, 2, 2.20, 2.40, 2.60, 2.80, and 3 GHz
- Dual processing server/workstation support
- Binary compatible with applications running on previous members of Intel's IA32 microprocessor line
- Intel® NetBurst™ micro-architecture
- Hyper-Threading Technology
 - Hardware support for multithreaded applications
- 400 MHz Front Side Bus
 - Bandwidth up to 3.2 GB/second
- Rapid Execution Engine: Arithmetic Logic Units (ALUs) run at twice the processor core frequency
- Hyper Pipelined Technology
- Advance Dynamic Execution
 - Very deep out-of-order execution
 - Enhanced branch prediction
- Level 1 Execution Trace Cache stores 12 K micro-ops and removes decoder latency from main execution loops
 - Includes 8 KB Level 1 data cache
- 512 KB Advanced Transfer L2 Cache (on-die, full speed Level 2 cache) with 8-way associativity and Error Correcting Code (ECC)
- Enables system support of up to 64 GB of physical memory
- Streaming SIMD Extensions 2 (SSE2)
 - 144 new instructions for double-precision floating point operations, media/video streaming, and secure transactions
- Enhanced floating point and multimedia unit for enhanced video, audio, encryption, and 3D performance
- Power Management capabilities
 - System Management mode
 - Multiple low-power states
- Advanced System Management Features
 - System Management Bus
 - Processor Information ROM (PIROM)
 - OEM Scratch EEPROM
 - Thermal Monitor
 - Machine Check Architecture (MCA)

The Intel® Xeon™ processor with 512 KB L2 cache is designed for high-performance dual-processor workstation and server applications. Based on the Intel® NetBurst™ micro-architecture and the new Hyper-Threading Technology, it is binary compatible with previous Intel Architecture (IA-32) processors. The Intel Xeon processor with 512 KB L2 cache is scalable to two processors in a multiprocessor system providing exceptional performance for applications running on advanced operating systems such as Windows XP*, Windows* 2000, Linux*, and UNIX*. The Intel Xeon processor with 512 KB L2 cache delivers compute power at unparalleled value and flexibility for powerful workstations, internet infrastructure, and departmental server applications. The Intel® NetBurst™ micro-architecture and Hyper-Threading Technology deliver outstanding performance and headroom for peak internet server workloads, resulting in faster response times, support for more users, and improved scalability.

Revision History

Date of Release	Revision No.	Description
January 2002	-001	Initial datasheet release.
April 2002	-002	Addition of 2.40 GHz Data
May 2002	-003	Updated Figures 10 and 11 Made PWRGOOD updates
September 2002	-004	Addition of 2.60 and 2.80 GHz Data Updated Thermal Requirements
September 2002	-005	Updated Thermal Requirements Updated Table 6, 7 Added Table 12
February 2003	-006	Added 3 GHz information. Edited definitions with current terminology. Added two TDP loadline figures in chapter 6. Added notes to signal definition tables for symmetric agents. Changed text., figures and tables for the boxed processor section.

1.0 Introduction

The Intel® Xeon™ processor with 512 KB L2 cache is based on the Intel® NetBurst™ micro-architecture, which operates at significantly higher clock speeds and delivers performance levels that are significantly higher than previous generations of IA-32 processors. While based on the Intel NetBurst micro-architecture, it maintains the tradition of compatibility with IA-32 software.

The Intel NetBurst micro-architecture features begin with innovative techniques that enhance processor execution such as Hyper Pipelined Technology, a Rapid Execution Engine, Advanced Dynamic Execution, enhanced Floating Point and Multimedia unit, and Streaming SIMD Extensions 2 (SSE2). The Hyper Pipelined Technology doubles the pipeline depth in the processor, allowing the processor to reach much higher core frequencies. The Rapid Execution Engine allows the two integer ALUs in the processor to run at twice the core frequency, which allows many integer instructions to execute in one half of the internal core clock period. The Advanced Dynamic Execution improves speculative execution and branch prediction internal to the processor. The floating point and multi-media units have been improved by making the registers 128 bits wide and adding a separate register for data movement. Finally, SSE2 adds 144 new instructions for double-precision floating point, SIMD integer, and memory management for improvements in video/multimedia processing, secure transactions, and visual internet applications.

Also part of the Intel NetBurst micro-architecture, the front side bus and caches on the Intel Xeon processor with 512 KB L2 cache provide tremendous throughput for server and workstation workloads. The 400 MHz front side bus provides a high-bandwidth pipeline to the system memory and I/O. It is a quad-pumped bus running off a 100 MHz front side bus clock making 3.2 Gigabytes per second (3,200 Megabytes per second) data transfer rates possible. The Execution Trace Cache is a level 1 cache that stores approximately twelve thousand decoded micro-operations, which removes the decoder latency from the main execution path and increases performance. The Advanced Transfer Cache is a 512 KB on-die level 2 cache running at the speed of the processor core providing increased bandwidth over previous micro-architectures.

In addition to the Intel NetBurst micro-architecture, the Intel Xeon processor with 512 KB L2 cache includes a groundbreaking new technology called Hyper-Threading technology, which enables multi-threaded software to execute tasks in parallel within the processor resulting in a more efficient, simultaneous use of processor resources. Server applications can realize increased performance from Hyper-Threading technology today, while workstation applications are expected to benefit from Hyper-Threading technology in the future through software and processor evolution. The combination of Intel NetBurst micro-architecture and Hyper-Threading technology delivers outstanding performance, throughput, and headroom for peak software workloads resulting in faster response times and improved scalability.

The Intel Xeon processor with 512 KB L2 cache is intended for high performance workstation and server systems with up to two processors on a single bus. The processor supports both uni- and dual-processor designs and includes manageability features. Components of the manageability features include an OEM EEPROM and Processor Information ROM that are accessible through a SMBus interface. The Processor Information ROM includes information that is relevant to the particular processor and system in which it is installed.

The Intel Xeon processor with 512 KB L2 cache is packaged in a 603-pin interposer micro-PGA (INT-mPGA) package, and utilizes a surface mount ZIF socket with 603 pins. Mechanical components used for attaching thermal solutions to the baseboard should have a high degree of commonality with the thermal solution components enabled for the Intel Xeon processor. Heatsinks and retention mechanisms have been designed with manufacturability as a high priority. Hence, mechanical assembly can be completed from the top of the baseboard.

The Intel Xeon processor with 512 KB L2 cache uses a scalable front side bus protocol referred to as the “front side bus” in this document. The processor front side bus utilizes a split-transaction, deferred reply protocol similar to that introduced by the Pentium® Pro processor front side bus, but is not compatible with the Pentium Pro processor front side bus. The Intel Xeon processor with 512 KB L2 cache front side bus is compatible with the Intel Xeon processor front side bus. The front side bus uses Source-Synchronous Transfer (SST) of address and data to improve performance, and transfers data four times per bus clock (4X data transfer rate). Along with the 4X data bus, the address bus can deliver addresses two times per bus clock and is referred to as a ‘double-clocked’ or 2X address bus. In addition, the Request Phase completes in one clock cycle. Working together, the 4X data bus and 2X address bus provide a data bus bandwidth of up to 3.2 Gigabytes per second. Finally, the front side bus also introduces transactions that are used to deliver interrupts.

Signals on the front side bus use Assisted GTL+ (AGTL+) level voltages which are fully described in the appropriate platform design guide (refer to [Section 1.3](#)).

1.1 Terminology

A ‘#’ symbol after a signal name refers to an active low signal, indicating a signal is in the asserted state when driven to a low level. For example, when RESET# is low, a reset has been requested. Conversely, when NMI is high, a nonmaskable interrupt has occurred. In the case of signals where the name does not imply an active state but describes part of a binary sequence (such as *address* or *data*), the ‘#’ symbol implies that the signal is inverted. For example, D[3:0] = ‘HLHL’ refers to a hex ‘A’, and D[3:0]# = ‘LHLH’ also refers to a hex ‘A’ (H= High logic level, L= Low logic level).

“Front Side Bus (FSB)” refers to the electrical interface that connects the processor to the chipset. Also referred to as the processor system bus or the system bus. All memory and I/O transactions as well as interrupt messages pass between the processor and chipset over the FSB.

1.1.1 Processor Packaging Terminology

Commonly used terms are explained here for clarification:

- **603-pin socket** - The connector which mates the Intel® Xeon™ processor with 512 KB L2 cache to the baseboard. The 603-pin socket is a surface mount technology (SMT), zero insertion force (ZIF) socket utilizing solder ball attachment to the platform. See the *603-Pin Socket Design Guidelines* for details regarding this socket.
- **Central Agent** - The central agent is the host bridge to the processor and is typically known as the chipset.
- **Flip Chip Ball Grid Array (FCBGA)** - Microprocessor packaging using “flip chip” design, where the processor is attached to the substrate face-down for better signal integrity, more efficient heat removal and lower inductance.
- **Front Side Bus** - Front Side Bus (FSB) is the electrical interface that connects the processor to the chipset. Also referred to as the processor system bus or the system bus. All memory and I/O transactions as well as interrupt messages pass between the processor and chipset over the FSB.
- **Intel® Xeon™ processor with 512 KB L2 cache** - The entire processor in its INT-mPGA package, including processor core in its FC-BGA package, integrated heat spreader (IHS), and interposer.

- **Integrated Heat Spreader (IHS)** - The surface used to attach a heatsink or other thermal solution to the processor.
- **Interposer** - The structure on which the processor core package and I/O pins are mounted.
- **OEM** - Original Equipment Manufacturer.
- **Processor core** - The processor's execution engine. All AC timing and signal integrity specifications are to the pads of the processor core.
- **Processor Information ROM (PIROM)** - An SMBus accessible memory device located on the processor interposer. This memory device contains information regarding the processor's features. This device is shared with a scratch EEPROM. The PIROM is programmed during the manufacturing and is write-protected. See [Section 7.4](#) for details on the PIROM.
- **Retention mechanism** - The support components that are mounted through the baseboard to the chassis to provide mechanical retention for the processor and heatsink assembly.
- **Scratch EEPROM (Electrically Erasable, Programmable Read-Only Memory)** - An SMBus accessible memory device located on the processor interposer. This memory device can be used by the OEM to store information useful for system management. See [Section 7.4](#) for details on the Scratch EEPROM.
- **SMBus** - System Management Bus. A two-wire interface through which simple system and power management related devices can communicate with the rest of the system. It is based on the principals of the operation of the I2C two-wire serial bus from Philips Semiconductor.
Note: "I2C is a two-wire communications bus/protocol developed by Philips. SMBus is a subset of the I2C bus/protocol and was developed by Intel. Implementations of the I2C bus/protocol or the SMBus bus/protocol may require licenses from various entities, including Philips Electronics N.V. and North American Philips Corporation."
- **Symmetric Agent** - A symmetric agent is a processor which shares the same I/O subsystem and memory array, and runs the same operating system as another processor in a system. Systems using symmetric agents are known as Symmetric Multiprocessing (SMP) systems. Intel® Xeon™ (DP - Dual Processor) processors should only be used in SMP systems which have two or fewer symmetric agents.

1.2 State of Data

The data contained in this document is subject to change. It is the best information that Intel is able to provide at the publication date of this document.

2.0 Electrical Specifications

2.1 Front Side Bus and GTLREF

Most Intel® Xeon™ processor with 512 KB L2 cache front side bus signals use Assisted Gunning Transceiver Logic (AGTL+) signaling technology. This signaling technology provides improved noise margins and reduced ringing through low voltage swings and controlled edge rates. The processor termination voltage level is V_{CC} , the operating voltage of the processor core. The use of a termination voltage that is determined by the processor core allows better voltage scaling on the processor front side bus. Because of the speed improvements to data and address busses, signal integrity and platform design methods become more critical than with previous processor families. Front side bus design guidelines are detailed in the appropriate platform design guide (refer to [Section 1.3](#)).

The AGTL+ inputs require a reference voltage (GTLREF) which is used by the receivers to determine if a signal is a logical 0 or a logical 1. GTLREF must be generated on the baseboard (See [Table 13](#) for GTLREF specifications). Termination resistors are provided on the processor silicon and are terminated to its core voltage (V_{CC}). The on-die termination resistors are a selectable feature and can be enabled or disabled via the ODTEN pin. For end bus agents, on-die termination can be enabled to control reflections on the transmission line. For middle bus agents, on-die termination must be disabled. Intel chipsets will also provide on-die termination, thus eliminating the need to terminate the bus on the baseboard for most AGTL+ signals. Refer to [Section 2.12](#) for details on ODTEN resistor termination requirements.

Note: Some AGTL+ signals do not include on-die termination and must be terminated on the baseboard. See [Table 4](#) for details regarding these signals.

The AGTL+ signals depend on incident wave switching. Therefore timing calculations for AGTL+ signals are based on flight time as opposed to capacitive deratings. Analog signal simulation of the front side bus, including trace lengths, is highly recommended when designing a system. Please refer to <http://developer.intel.com> to obtain the *Intel® Xeon™ Processor with 512 KB L2 Cache Signal Integrity Models*.

2.2 Power and Ground Pins

For clean on-chip power distribution, the Intel Xeon processor with 512 KB L2 cache has 190 V_{CC} (power) and 189 V_{SS} (ground) inputs. All V_{CC} pins must be connected to the system power plane, while all V_{SS} pins must be connected to the system ground plane. The processor V_{CC} pins must be supplied the voltage determined by the processor VID (Voltage ID) pins.

2.3 Decoupling Guidelines

Due to its large number of transistors and high internal clock speeds, the processor is capable of generating large average current swings between low and full power states. This may cause voltages on power planes to sag below their minimum values if bulk decoupling is not adequate. Larger bulk storage (C_{BULK}), such as electrolytic capacitors, supply current during longer lasting changes in current demand by the component, such as coming out of an idle condition. Similarly, they act as a storage well for current when entering an idle condition from a running condition.

Care must be taken in the baseboard design to ensure that the voltage provided to the processor remains within the specifications listed in [Table 6](#). Failure to do so can result in timing violations or reduced lifetime of the component. For further information and guidelines, refer to the appropriate platform design guidelines.

2.3.1 V_{CC} Decoupling

Regulator solutions need to provide bulk capacitance with a low Effective Series Resistance (ESR) and the baseboard designer must ensure a low interconnect resistance from the regulator (or VRM pins) to the 603-pin socket. Bulk decoupling may be provided on the voltage regulation module (VRM) to meet help meet the large current swing requirements. The remaining decoupling is provided on the baseboard. The power delivery path must be capable of delivering enough current while maintaining the required tolerances (defined in [Table 6](#)). For further information regarding power delivery, decoupling, and layout guidelines, refer to the appropriate platform design guidelines.

2.3.2 Front Side Bus AGTL+ Decoupling

The Intel® Xeon™ processor with 512 KB L2 cache integrates signal termination on the die as well as part of the required high frequency decoupling capacitance on the processor package. However, additional high frequency capacitance must be added to the baseboard to properly decouple the return currents from the front side bus. Bulk decoupling must also be provided by the baseboard for proper AGTL+ bus operation. Decoupling guidelines are described in the appropriate platform design guidelines.

2.4 Front Side Bus Clock (BCLK[1:0]) and Processor Clocking

BCLK[1:0] directly controls the front side bus interface speed as well as the core frequency of the processor. As in previous generation processors, the processor core frequency is a multiple of the BCLK[1:0] frequency. The maximum processor bus ratio multiplier will be set during manufacturing. The default setting will equal the maximum speed for the processor.

The BCLK[1:0] inputs directly control the operating speed of the front side bus interface. The processor core frequency is configured during reset by using values stored internally during manufacturing. The stored value sets the highest bus fraction at which the particular processor can operate.

Clock multiplying within the processor is provided by the internal PLL, which requires a constant frequency BCLK[1:0] input with exceptions for spread spectrum clocking. Processor DC and AC specifications for the BCLK[1:0] inputs are provided in [Table 7](#) and [Table 14](#), respectively. These specifications must be met while also meeting signal integrity requirements as outlined in [Chapter 3.0](#). The processor utilizes a differential clock. Details regarding BCLK[1:0] driver specifications are provided in the *CK00 Clock Synthesizer/Driver Design Guidelines*. [Table 1](#) contains the supported bus fraction ratios and their corresponding core frequencies.

Table 1. Front Side Bus-to-Core Frequency Ratio

Front Side Bus-to-Core Frequency Ratio	Core Frequency
1/16	1.60 GHz
1/17	1.70 GHz
1/18	1.80 GHz
1/19	1.90 GHz

1/22	2.20 GHz
1/24	2.40 GHz
1/26	2.60 GHz
1/28	2.80 GHz
1/30	3 GHz

2.4.1 Bus Clock

The front side bus frequency is set to the maximum supported by the individual processor. BSEL[1:0] are outputs used to select the front side bus frequency. Table 2 defines the possible combinations of the signals and the frequency associated with each combination. The frequency is determined by the processor(s), chipset, and clock synthesizer. All front side bus agents must operate at the same frequency. Individual processors will only operate at their specified front side bus clock frequency, (100 MHz for present generation processors).

Baseboards designed for the Intel® Xeon™ processor employ a 100 MHz front side bus clock. On these baseboards, BSEL[1:0] are considered ‘reserved’ at the processor socket. No change is required for operation with the Intel® Xeon™ processor with 512 KB L2 cache. Operation will default to 100 MHz.

Table 2. Front Side Bus Clock Frequency Select Truth Table for BSEL[1:0]

BSEL1	BSEL0	Bus Clock Frequency
L	L	100 MHz
L	H	Reserved
H	L	Reserved
H	H	Reserved

2.5 PLL Filter

V_{CCA} and $V_{CCIOPLL}$ are power sources required by the processor PLL clock generator. This requirement is identical to that of the Intel Xeon processor. Since these PLLs are analog in nature, they require quiet power supplies for minimum jitter. Jitter is detrimental to the system: it degrades external I/O timings as well as internal core timings (i.e. maximum frequency). To prevent this degradation, these supplies must be low pass filtered from V_{CC} . A typical filter topology is shown in Figure 1.

The AC low-pass requirements, with input at V_{CC} and output measured across the capacitor (C_A or C_{IO} in Figure 1), is as follows:

- < 0.2 dB gain in pass band
- < 0.5 dB attenuation in pass band < 1 Hz (see DC drop in next set of requirements)
- > 34 dB attenuation from 1 MHz to 66 MHz
- > 28 dB attenuation from 66 MHz to core frequency

The filter requirements are illustrated in Figure 2. For recommendations on implementing the filter refer to the appropriate platform design guidelines.

Figure 1. Typical $V_{CCIOPLL}$, V_{CCA} and V_{SSA} Power Distribution

Figure 2. Phase Lock Loop (PLL) Filter Requirements

NOTES:

1. Diagram not to scale.
2. No specifications for frequencies beyond f_{core} (core frequency).
3. f_{peak} , if existent, should be less than 0.05 MHz.

2.5.1 Mixing Processors

Intel only supports those processor combinations operating with the same front side bus frequency, core frequency, VID settings, and cache sizes. Not all operating systems can support multiple processors with mixed frequencies. Intel does not support or validate operation of processors with different cache sizes. Mixing processors of different steppings but the same model (as per CPUID instruction) is supported, and is outlined in the *Intel® Xeon™ Processor Specification Update*. Additional details are provided in AP-485, the *Intel Processor Identification and the CPUID Instruction* application note.

Unlike previous Intel® Xeon™ processors, the Intel Xeon processor with 512 KB L2 cache does not sample the pins IGNNE#, LINT[0]/INTR, LINT[1]/NMI, and A20M# to establish the core to front side bus ratio. Rather, the processor runs at its tested frequency at initial power-on. If the processor needs to run at a lower core frequency, as must be done when a higher speed processor is added to a system that contains a lower frequency processor, the system BIOS is able to effect the change in the core to front side bus ratio.

2.6 Voltage Identification

The VID specification for the processor is defined in this datasheet, and is supported by power delivery solutions designed according to the *Dual Intel® Xeon™ Processor Voltage Regulator Down (VRD) Design Guidelines*, *VRM 9.0 DC-DC Converter Design Guidelines*, and *VRM 9.1 DC-DC Converter Design Guidelines*. The minimum voltage is provided in [Table 6](#), and varies with processor frequency. This allows processors running at a higher frequency to have a relaxed minimum voltage specification. The specifications have been set such that one voltage regulator design can work with all supported processor frequencies.

Note that the VID pins will drive valid and correct logic levels when the Intel® Xeon™ processor with 512 KB L2 cache is provided with a valid voltage applied to the SM_V_{CC} pins. **SM_V_{CC} must be correct and stable prior to enabling the output of the VRM that supplies V_{CC}.** Similarly, the output of the VRM must be disabled before SM_V_{CC} becomes invalid. Refer to [Figure 19](#) for details.

The processor uses five voltage identification pins, VID[4:0], to support automatic selection of processor voltages. [Table 3](#) specifies the voltage level corresponding to the state of VID[4:0]. A '1' in this table refers to a high voltage and a '0' refers to low voltage level. If the processor socket is empty (VID[4:0] = 11111), or the VRD or VRM cannot supply the voltage that is requested, it must disable its voltage output. For further details, see the *Dual Intel® Xeon™ Processor Voltage Regulator Down (VRD) Design Guidelines*, or *VRM 9.0 DC-DC Converter Design Guidelines* or the *VRM 9.1 DC-DC Converter Design Guidelines*.

Table 3. Voltage Identification Definition

Processor Pins					
VID4	VID3	VID2	VID1	VID0	V _{CC_VID} (V)
1	1	1	1	1	VRM output off
1	1	1	1	0	1.100
1	1	1	0	1	1.125
1	1	1	0	0	1.150
1	1	0	1	1	1.175
1	1	0	1	0	1.200
1	1	0	0	1	1.225
1	1	0	0	0	1.250
1	0	1	1	1	1.275
1	0	1	1	0	1.300
1	0	1	0	1	1.325
1	0	1	0	0	1.350
1	0	0	1	1	1.375
1	0	0	1	0	1.400
1	0	0	0	1	1.425
1	0	0	0	0	1.450
0	1	1	1	1	1.475
0	1	1	1	0	1.500
0	1	1	0	1	1.525
0	1	1	0	0	1.550
0	1	0	1	1	1.575
0	1	0	1	0	1.600
0	1	0	0	1	1.625
0	1	0	0	0	1.650
0	0	1	1	1	1.675
0	0	1	1	0	1.700
0	0	1	0	1	1.725
0	0	1	0	0	1.750
0	0	0	1	1	1.775
0	0	0	1	0	1.800
0	0	0	0	1	1.825
0	0	0	0	0	1.850

2.6.1 Mixing Processors of Different Voltages

Mixing processors operating with different VID settings (voltages) is not supported and will not be validated by Intel.

2.7 Reserved Or Unused Pins

All Reserved pins must remain unconnected on the system baseboard. Connection of these pins to V_{CC} , V_{SS} , or to any other signal (including one another) can result in component malfunction or incompatibility with future processors. See [Chapter 5.0](#) for a pin listing of the processor and for the location of all Reserved pins.

For reliable operation, unused inputs or bidirectional signals should always be connected to an appropriate signal level. In a system-level design, on-die termination has been included on the processor to allow signal termination to be accomplished by the processor silicon. Most unused AGTL+ inputs should be left as no connects, as AGTL+ termination is provided on the processor silicon. However, see [Table 4](#) for details on AGTL+ signals that do not include on-die termination. Unused active high inputs should be connected through a resistor to ground (V_{SS}). Unused outputs can be left unconnected, however this may interfere with some TAP functions, complicate debug probing, and prevent boundary scan testing. A resistor must be used when tying bidirectional signals to power or ground. When tying any signal to power or ground, a resistor will also allow for system testability. For unused AGTL+ input or I/O signals, use pull-up resistors of the same value for the on-die termination resistors (R_{TT}). See [Table 13](#).

TAP, Asynchronous GTL+ inputs, and Asynchronous GTL+ outputs do not include on-die termination. Inputs and all used outputs must be terminated on the baseboard. Unused outputs may be terminated on the baseboard or left unconnected. Note that leaving unused outputs unterminated may interfere with some TAP functions, complicate debug probing, and prevent boundary scan testing. Signal termination for these signal types is discussed in the *ITP700 Debug Port Design Guide*.

All TESTHI[6:0] pins should be individually connected to V_{CC} via a pull-up resistor which matches the trace impedance within $\pm 10 \Omega$. TESTHI[3:0] and TESTHI[6:5] may all be tied together and pulled up to V_{CC} with a single resistor if desired. However, utilization of boundary scan test will not be functional if these pins are connected together. TESTHI4 must always be pulled up independently from the other TESTHI pins. For optimum noise margin, all pull-up resistor values used for TESTHI[6:0] pins should have a resistance value within 20 percent of the impedance of the baseboard transmission line traces. For example, if the trace impedance is 50Ω , then a pull-up resistor value between 40 and 60Ω should be used. The TESTHI[6:0] termination recommendations provided in the *Intel® Xeon™ Processor Datasheet* are also suitable for the Intel® Xeon™ processor with 512 KB L2 cache. However, Intel recommends new designs or designs undergoing design updates follow the trace impedance matching termination guidelines outlined in this section.

2.8 Front Side Bus Signal Groups

In order to simplify the following discussion, the front side bus signals have been combined into groups by buffer type. AGTL+ input signals have differential input buffers, which use GTLREF as a reference level. In this document, the term “AGTL+ Input” refers to the AGTL+ input group as well as the AGTL+ I/O group when receiving. Similarly, “AGTL+ Output” refers to the AGTL+ output group as well as the AGTL+ I/O group when driving.

With the implementation of a source synchronous data bus comes the need to specify two sets of timing parameters. One set is for common clock signals whose timings are specified with respect to rising edge of BCLK0 (ADS#, HIT#, HITM#, etc.) and the second set is for the source synchronous signals which are relative to their respective strobe lines (data and address) as well as

rising edge of BCLK0. Asynchronous signals are still present (A20M#, IGNNE#, etc.) and can become active at any time during the clock cycle. Table 4 identifies which signals are common clock, source synchronous and asynchronous.

Table 4. Front Side Bus Signal Groups

Signal Group	Type	Signals ¹	
AGTL+ Common Clock Input	Synchronous to BCLK[1:0]	BPRI#, BR[3:1]# ^{3,4} , DEFER#, RESET# ⁴ , RS[2:0]#, RSP#, TRDY#	
AGTL+ Common Clock I/O	Synchronous to BCLK[1:0]	ADS#, AP[1:0]#, BINIT# ⁷ , BNR# ⁷ , BPM[5:0]# ² , BR0# ² , DBSY#, DP[3:0]#, DRDY#, HIT# ⁷ , HITM# ⁷ , LOCK#, MCERR# ⁷	
AGTL+ Source Synchronous I/O	Synchronous to assoc. strobe		
		Signals	Associated Strobe
		REQ[4:0]#,A[16:3]# ⁶	ADSTB0#
		A[35:17]# ⁵	ADSTB1#
		D[15:0]#, DBI0#	DSTBP0#, DSTBN0#
		D[31:16]#, DBI1#	DSTBP1#, DSTBN1#
		D[47:32]#, DBI2#	DSTBP2#, DSTBN2#
D[63:48]#, DBI3#	DSTBP3#, DSTBN3#		
AGTL+ Strobes	Synchronous to BCLK[1:0]	ADSTB[1:0]#, DSTBP[3:0]#, DSTBN[3:0]#	
Asynchronous GTL+ Input ⁴	Asynchronous	A20M# ⁵ , IGNNE# ⁵ , INIT# ⁶ , LINT0/INTR ⁵ , LINT1/NMI ⁵ , SMI# ⁶ , SLP#, STPCLK#	
Asynchronous GTL+ Output ⁴	Asynchronous	FERR#, IERR#, THERMTRIP#, PROCHOT#	
Front Side Bus Clock	Clock	BCLK1, BCLK0	
TAP Input ²	Synchronous to TCK	TCK, TDI, TMS, TRST#	
TAP Output ²	Synchronous to TCK	TDO	
SMBus Interface ⁸	Synchronous to SM_CLK	SM_EP_A[2:0], SM_TS_A[1:0], SM_DAT, SM_CLK, SM_ALERT#, SM_WP	
Power/Other	Power/Other	BSEL[1:0], COMP[1:0], GTLREF, ODTEN, Reserved, SKTOCC#, TESTHI[6:0],VID[4:0], V _{CC} , SM_V _{CC} ⁹ , V _{CCA} , V _{CCIOPLL} , V _{SSA} , V _{SS} , V _{CCSENSE} , V _{SSSENSE} , PWRGOOD	

1. Refer to Section 5.2 for signal descriptions.
2. These signal groups are not terminated by the processor. Refer the *ITP700 Debug Port Design Guide* and corresponding Design Guide for termination requirements and further details.
3. The Intel® Xeon™ processor with 512 KB L2 cache utilizes only BR0# and BR1#. BR2# and BR3# are not driven by the processor but must be terminated to V_{CC}. For additional details regarding the BR[3:0]# signals, see Section 5.2 and Section 7.1 and the appropriate Platform Design Guidelines.
4. These signals do not have on-die termination. Refer to corresponding Platform Design Guidelines for termination requirements.
5. **Note that Reset initialization function of these pins is now a software function on the Intel® Xeon™ processor with 512 KB L2 cache.**
6. The value of these pins during the active-to-inactive edge of RESET# to determine processor configuration options. See Section 7.1 for details.
7. These signals may be driven simultaneously by multiple agents (wired-or).
8. These signals are not terminated by the processor's on-die termination. However, some signals in this group include termination on the processor interposer. See Section 7.4 for details.

9. **SM_Vcc is required** for correct VID logic operation of the Intel® Xeon™ processor with 512 KB L2 cache. Refer to [Figure 19](#) for details.

2.9 Asynchronous GTL+ Signals

The Intel® Xeon™ processor with 512 KB L2 cache does not utilize CMOS voltage levels on any signals that connect to the processor silicon. As a result, legacy input signals such as A20M#, IGNNE#, INIT#, LINT0/INTR, LINT1/NMI, SMI#, SLP#, and STPCLK# utilize GTL+ input buffers. Legacy output FERR#/PBE# and other non-AGTL+ signals IERR#, THERMTRIP# and PROCHOT# utilize GTL+ output buffers. All of these asynchronous GTL+ signals follow the same DC requirements as AGTL+ signals, however the outputs are not driven high (during the logical 0-to-1 transition) by the processor (the major difference between GTL+ and AGTL+). Asynchronous GTL+ signals do not have setup or hold time specifications in relation to BCLK[1:0]. However, all of the asynchronous GTL+ signals are required to be asserted for at least two BCLKs in order for the processor to recognize them. See [Table 10](#) and [Table 17](#) for the DC and AC specifications for the asynchronous GTL+ signal groups.

SMBus signals are derived from components mounted on the processor interposer along with the processor silicon. The required SM_VCC for these signals is 3.3 volts. See [Section 7.4](#) for further details.

2.10 Maximum Ratings

[Table 5](#) lists the processor's maximum environmental stress ratings. Functional operation at the absolute maximum and minimum is neither implied nor guaranteed. The processor should not receive a clock while subjected to these conditions. Functional operating parameters are listed in the AC and DC tables. Extended exposure to the maximum ratings may affect device reliability. Furthermore, although the processor contains protective circuitry to resist damage from static electric discharge, one should always take precautions to avoid high static voltages or electric fields.

Table 5. Processor Absolute Maximum Ratings

Symbol	Parameter	Min	Max	Unit	Notes
T _{STORAGE}	Processor storage temperature	-40	85	°C	2
V _{CC}	Any processor supply voltage with respect to V _{SS}	-0.3	1.75	V	1
V _{inAGTL+}	AGTL+ buffer DC input voltage with respect to V _{SS}	-0.1	1.75	V	
V _{inGTL+}	Async GTL+ buffer DC input voltage with respect to V _{SS}	-0.1	1.75	V	
V _{inSMBus}	SMBus buffer DC input voltage with respect to V _{SS}	-0.3	6.0	V	
I _{VID}	Max VID pin current		5	mA	

1. This rating applies to any pin of the processor.
2. Contact Intel for storage requirements in excess of one year.

2.11 Processor DC Specifications

The processor DC specifications in this section are defined at the processor core (pads) unless noted otherwise. See [Section 5.1](#) for the processor pin listings and [Section 5.2](#) for the signal definitions. The voltage and current specifications for all versions of the processor are detailed in [Table 6](#). For platform planning refer to [Figure 3](#). Notice that the graphs include Thermal Design Power (TDP) associated with the maximum current levels. The DC specifications for the AGTL+ signals are listed in [Table 8](#).

The front side bus clock signal group and the SMBus interface signal group are detailed in [Table 7](#) and [Table 11](#), respectively. The DC specifications for these signal groups are listed in [Table 9](#).

[Table 6](#) through [Table 11](#) list the processor DC specifications and are valid only while meeting specifications for case temperature (T_{CASE} as specified in [Chapter 6.0](#)), clock frequency, and input voltages. Care should be taken to read all notes associated with each parameter.

Table 6. Voltage and Current Specifications

Symbol	Parameter	Core Freq	Min	Typ	Max	VID	Unit	Notes ¹
V _{CC}	V _{CC} for Intel Xeon processor with 512 KB L2 cache	1.80 GHz	1.361	Refer to Figure 3	1.465	1.5	V	2, 3, 4, 11, 12
		2.0 GHz	1.357		1.463	1.5	V	2, 3, 4, 11, 12
		2.20 GHz	1.352		1.46	1.5	V	2, 3, 4, 11, 12
		2.40 GHz	1.347		1.458	1.5	V	2, 3, 4, 11, 12
		2.60 GHz	1.339		1.453	1.5	V	2, 3, 4, 11, 12
		2.80 GHz	1.335		1.450	1.5	V	2, 3, 4, 11, 12
		3 GHz	1.356		1.467	1.525	V	2, 3, 4, 11, 12
SM_V _{CC}	SMBus supply voltage	All freq.	3.135	3.30	3.465		V	8
I _{CC}	I _{CC} for Intel Xeon processor with 512 KB L2 cache	1.8 GHz			42.4		A	4, 5
		2 GHz			45.3		A	4, 5
		2.20 GHz			48.1		A	4, 5
		2.40 GHz			51		A	4, 5
		2.60 GHz			56.1		A	4, 5
		2.80 GHz			59.1		A	4, 5
		3 GHz			69.1		A	4, 5
I _{CC_PLL}	I _{CC} for PLL power pins	All freq			60		mA	9
I _{CC_SMBus}	I _{CC} for SMBus power supply	All freq.		100.0	122.5		mA	8
I _{CC_GTLREF}	I _{CC} for GTLREF pins	All freq			15		μA	10
I _{SGnt} /I _{SLP}	I _{CC} Stop-Grant/Sleep	All freq			25		A	6
I _{TCC}	I _{CC} TCC active	All freq			18.6		A	7

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processors.
2. These voltages are targets only. A variable voltage source should exist on systems in the event that a different voltage is required. See [Section 2.6](#) and [Table 3](#) for more information.
3. The voltage specification requirements are measured across vias on the platform for the V_{CC_SENSE} and V_{SS_SENSE} pins close to the socket with a 100 MHz bandwidth oscilloscope, 1.5 pF maximum probe capacitance, and 1 milliohm minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled in the scope probe.
4. The processor should not be subjected to any static V_{CC} level that exceeds the V_{CC_MAX} associated with any particular current. Moreover, V_{CC} should never exceed V_{CC_VID}. Failure to adhere to this specification can shorten the processor lifetime.
5. Maximum current is defined at V_{CC_MAX}.
6. The current specified is also for AutoHALT State.
7. The maximum instantaneous current the processor will draw while the thermal control circuit is active as indicated by the assertion of PROCHOT#.
8. **SM_V_{CC}** is required for correct operation of the processor VID logic. Refer to [Figure 19](#) for details.
9. This specification applies to the PLL power pins VCCA and VCCIOPLL. See [Section 2.5](#) for details. This parameter is based on design characterization and is not tested.
10. This specification applies to each GTLREF pin.
11. The loadlines specify voltage limits at the die measured at V_{CC_SENSE} and V_{SS_SENSE} pins. Voltage regulation feedback for voltage regulator circuits must be taken from processor V_{CC} and V_{SS} pins.
12. Adherence to this loadline specification is required to ensure reliable processor operation.

Figure 3. Intel® Xeon™ Processor with 512 KB L2 Cache Voltage-Current (VID = 1.5V)

Figure 4. Intel® Xeon™ Processor with 512 KB L2 Cache Voltage-Current (VID = 1.525V)

Table 7. Front Side Bus Differential BCLK Specifications

Symbol	Parameter	Min	Typ	Max	Unit	Figure	Notes ₁
V_L	Input Low Voltage	-0.150	0.000	N/A	V	7	
V_H	Input High Voltage	0.660	0.710	0.850	V	7	
$V_{CROSS(abs)}$	Absolute Crossing Point	0.250	N/A	0.550	V	7, 8	2,8
$V_{CROSS(rel)}$	Relative Crossing Point	$0.250 + 0.5(V_{Havg} - 0.710)$	N/A	$0.550 + 0.5(V_{Havg} - 0.710)$	V	7, 8	2,3,8,9
$\Delta V_{CROSS S}$	Range of Crossing Points	N/A	N/A	0.140	V	7, 8	2,10
V_{OV}	Overshoot	N/A	N/A	$V_H + 0.3$	V	7	4
V_{US}	Undershoot	-0.300	N/A	N/A	V	7	5

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. Crossing voltage is defined as the instantaneous voltage value when the rising edge of BCLK0 equals the falling edge of BCLK1.
3. V_{Havg} is the statistical average of the V_H measured by the oscilloscope.

4. Overshoot is defined as the absolute value of the maximum voltage.
5. Undershoot is defined as the absolute value of the minimum voltage.
6. Ringback Margin is defined as the absolute voltage difference between the maximum Rising Edge Ringback and the maximum Falling Edge Ringback.
7. Threshold Region is defined as a region entered around the crossing point voltage in which the differential receiver switches. It includes input threshold hysteresis.
8. The crossing point must meet the absolute and relative crossing point specifications simultaneously.
9. V_{Havg} can be measured directly using "Vtop" on Agilent* scopes and "High" on Tektronix* scopes.
10. ΔV_{CROSS} is defined as the total variation of all crossing voltages as defined in note 2.

Table 8. AGTL+ Signal Group DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes 1,7
V_{IH}	Input High Voltage	$1.10 * GTLREF$	V_{CC}	V	2, 4, 6
V_{IL}	Input Low Voltage	0.0	$0.90 * GTLREF$	V	3, 6
V_{OH}	Output High Voltage	N/A	V_{CC}	V	4, 6
I_{OL}	Output Low Current	N/A	$\frac{V_{CC}}{(0.50 * R_{TT_min} + R_{ON_min})} = 50$	mA	6
I_{HI}	Pin Leakage High	N/A	100	μA	9
I_{LO}	Pin Leakage Low	N/A	500	μA	8
R_{ON}	Buffer On Resistance	7	11	Ω	5, 7

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. V_{IH} is defined as the minimum voltage level at a receiving agent that will be interpreted as a logical high value.
3. V_{IL} is defined as the maximum voltage level at a receiving agent that will be interpreted as a logical low value.
4. V_{IH} and V_{ON} may experience excursions above V_{CC} . However, input signal drivers must comply with the signal quality specifications in [Chapter 3.0](#).
5. Refer to the *Intel® Xeon™ Processor with 512 KB L2 Cache Signal Integrity Models* for I/V characteristics.
6. The V_{CC} referred to in these specifications refers to instantaneous V_{CC} .
7. V_{OL_MAX} of 0.450 V is guaranteed when driving into a test load as indicated in [Figure 5](#), with R_{TT} enabled.
8. Leakage to V_{CC} with pin held at 300 mV.
9. Leakage to V_{SS} with pin held at V_{CC} .

Table 9. TAP and PWRGOOD Signal Group DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes 1, 2
V_{HYS}	TAP Input Hysteresis	200	300		8
V_{T+}	TAP input low to high threshold voltage	$0.5 * (V_{CC} + V_{HYS_MIN})$	$0.5 * (V_{CC} + V_{HYS_MAX})$		5
V_{T-}	TAP input high to low threshold voltage	$0.5 * (V_{CC} - V_{HYS_MAX})$	$0.5 * (V_{CC} - V_{HYS_MIN})$		5
V_{OH}	Output High Voltage	N/A	V_{CC}	V	3, 5
I_{OL}	Output Low Current		40	mA	6, 7
I_{HI}	Pin Leakage High	N/A	100	μA	10
I_{LO}	Pin Leakage Low	N/A	500	μA	9
R_{ON}	Buffer On Resistance	8.75	13.75	Ω	4

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. All outputs are open drain

3. TAP signal group must meet the system signal quality specification in Chapter 3.0.
4. Refer to the *Intel® Xeon™ Processor with 512 KB L2 Cache Signal Integrity Models* for I/V characteristics.
5. The V_{CC} referred to in these specifications refers to instantaneous V_{CC} .
6. The maximum output current is based on maximum current handling capability of the buffer and is not specified into the test load.
7. V_{OL_MAX} of 0.300V is guaranteed when driving a test load.
8. V_{HYS} represents the amount of hysteresis, nominally centered about $0.5 \cdot V_{CC}$, for all TAP inputs.
9. Leakage to V_{CC} with Pin held at 300 mV.
10. Leakage to V_{SS} with pin held at V_{CC} .

Table 10. Asynchronous GTL+ Signal Group DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes ^{1, 7}
V_{IH}	Input High Voltage	$1.10 \cdot GTLREF$	V_{CC}	V	3, 5, 7
V_{IL}	Input Low Voltage	0.0	$0.90 \cdot GTLREF$	V	4, 6
V_{OH}	Output High Voltage	N/A	V_{CC}	V	2, 5, 7
I_{OL}	Output Low Current		50	mA	8, 9
I_{HI}	Pin Leakage High	N/A	100	μA	11
I_{LO}	Pin Leakage Low	N/A	500	μA	10
R_{ON}	Buffer On Resistance	7	11	Ω	6

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. All outputs are open drain
3. V_{IH} is defined as the minimum voltage level at a receiving agent that will be interpreted as a logical high value.
4. V_{IL} is defined as the maximum voltage level at a receiving agent that will be interpreted as a logical low value.
5. V_{IH} and V_{OH} may experience excursions above V_{CC} . However, input signal drivers must comply with the signal quality specifications in Chapter 3.0.
6. Refer to the *Intel® Xeon™ Processor with 512 KB L2 Cache Signal Integrity Models* for I/V characteristics.
7. The V_{CC} referred to in these specifications refers to instantaneous V_{CC} .
8. The maximum output current is based on maximum current handling capability of the buffer and is not specified into the test load.
9. V_{OL_MAX} of 0.450 V is guaranteed when driving into a test load as indicated in Figure 5, with R_{TT} enabled.
10. Leakage to V_{CC} with Pin held at 300 mV.
11. Leakage to V_{SS} with pin held at V_{CC} .

Table 11. SMBus Signal Group DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes ^{1, 2, 3}
V_{IL}	Input Low Voltage	-0.30	$0.30 \cdot SM_V_{CC}$	V	
V_{IH}	Input High Voltage	$0.70 \cdot SM_V_{CC}$	3.465	V	
V_{OL}	Output Low Voltage	0	0.400	V	
I_{OL}	Output Low Current	N/A	3.0	mA	
I_{LI}	Input Leakage Current	N/A	± 10	μA	
I_{LO}	Output Leakage Current	N/A	± 10	μA	
C_{SMB}	SMBus Pin Capacitance		15.0	pF	4

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. These parameters are based on design characterization and are not tested.
3. All DC specifications for the SMBus signal group are measured at the processor pins.
4. Platform designers may need this value to calculate the maximum loading of the SMBus and to determine maximum rise and fall times for SMBus signals.

Table 12. BSEL[1:0] and VID[4:0] DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes ¹
R _{on} (BSEL)	Buffer On Resistance	9.2	14.3	Ω	2
R _{on} (VID)	Buffer On Resistance	7.8	12.8	Ω	2
I _{HI}	Pin Leakage Hi	N/A	100	μA	3

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.

2. These parameters are not tested and are based on design simulations.

3. Leakage to V_{SS} with pin held at 2.50V.

2.12 AGTL+ Front Side Bus Specifications

Routing topologies are dependent on the number of processors supported and the chipset used in the design. Please refer to the appropriate platform design guidelines. In most cases, termination resistors are not required as these are integrated into the processor. See Table 4 for details on which AGTL+ signals do not include on-die termination. The termination resistors are enabled or disabled through the ODTEN pin. To enable termination, this pin should be pulled up to V_{CC} through a resistor and to disable termination, this pin should be pulled down to V_{SS} through a resistor. For optimum noise margin, all pull-up and pull-down resistor values used for the ODTEN pin should have a resistance value within 20 percent of the impedance of the baseboard transmission line traces. For example, if the trace impedance is 50 Ω, then a value between 40 and 60 Ω should be used. The processor's on-die termination must be enabled for the end agent only. Please refer to Table 13 for termination resistor values. For more details on platform design see the appropriate platform design guidelines.

Valid high and low levels are determined by the input buffers via comparing with a reference voltage called GTLREF.

Table 13 lists the GTLREF specifications. The AGTL+ reference voltage (GTLREF) should be generated on the baseboard using high precision voltage divider circuits. It is important that the baseboard impedance is held to the specified tolerance, and that the intrinsic trace capacitance for the AGTL+ signal group traces is known and well-controlled. For more details on platform design see the appropriate platform design guidelines.

Table 13. AGTL+ Bus Voltage Definitions

Symbol	Parameter	Min	Typ	Max	Units	Notes ¹
GTLREF	Bus Reference Voltage	$\frac{2}{3} * V_{CC} - 2\%$	$\frac{2}{3} * V_{CC}$	$\frac{2}{3} * V_{CC} + 2\%$	V	2, 3, 6
GTLREF New Design	Bus Reference Voltage	$0.63 * V_{CC} - 2\%$	$0.63 * V_{CC}$	$0.63 * V_{CC} + 2\%$	V	2, 3, 6,
R _{TT}	Termination Resistance	36	41	46	Ω	4
R _{TT} New Design	Termination Resistance	45	50	55	Ω	4, 8
COMP[1:0]	COMP Resistance	42.77	43.2	43.63	Ω	5, 7

Table 13. AGTL+ Bus Voltage Definitions

COMP[1:0] New Design	COMP Resistance	49.55	50	50.45	Ω	5, 7, 8
----------------------------	-----------------	-------	----	-------	----------	---------

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. The tolerances for this specification have been stated generically to enable system designer to calculate the minimum values across the range of V_{CC} .
3. GTLREF is generated from V_{CC} on the baseboard by a voltage divider of 1 percent resistors. Refer to the appropriate platform design guidelines for implementation details.
4. R_{TT} is the on-die termination resistance measured from V_{CC} to $1/3 V_{CC}$ at the AGTL+ output driver. Refer to the Intel® Xeon™ Processor with 512 KB L2 Cache Signal Integrity Models for I/V characteristics.
5. COMP resistors are pull downs to V_{SS} provided on the baseboard with 1% tolerance. See the appropriate platform design guidelines for implementation details.
6. The V_{CC} referred to in these specifications refers to instantaneous V_{CC} .
7. The COMP resistance value varies by platform. Refer to the appropriate platform design guideline for the recommended COMP resistance value.
8. The values for R_{TT} and COMP noted as 'New Designs' apply to designs that are optimized for the Intel® Xeon™ processor with 512 KB L2 cache. Refer to the appropriate platform design guideline for the recommended COMP resistance value.
9. This specification applies to the Intel® Xeon™ Processor with 512 KB L2 Cache when implemented in platforms that do not include forward compatibility with future processors.
10. This specification applies to the Intel Xeon Processor with 512 KB L2 Cache when implemented in platforms that include forward compatibility with future processors.

2.13 Front Side Bus AC Specifications

The processor front side bus timings specified in this section are defined at the processor core (pads). See [Section 5.0](#) for the pin listing and signal definitions.

[Table 14](#) through [Table 20](#) list the AC specifications associated with the processor front side bus.

All AGTL+ timings are referenced to GTLREF for both '0' and '1' logic levels unless otherwise specified.

The timings specified in this section should be used in conjunction with the signal integrity models provided by Intel. These signal integrity models, which include package information, are available for the Intel® Xeon™ processor with 512 KB L2 cache in IBIS format. AGTL+ layout guidelines are also available in the appropriate platform design guidelines.

Note: Care should be taken to read all notes associated with a particular timing parameter

Table 14. Front Side Bus Differential Clock Specifications

T# Parameter	Min	Nom	Max	Unit	Figure	Notes
Front Side Bus Clock Frequency			100.0	MHz		1, 2
T1: BCLK[1:0] Period	10.00		10.20	nS	7	1, 3
T2: BCLK[1:0] Period Stability	N/A		150	pS		1, 4, 5
T3: T_{PH} BCLK[1:0] Pulse High Time	3.94	5	6.12	nS	7	1
T4: T_{PL} BCLK[1:0] Pulse Low Time	3.94	5	6.12	nS	7	1
T5: BCLK[1:0] Rise Time	175		700	pS	7	1, 6
T6: BCLK[1:0] Fall Time	175		700	pS	7	1, 6

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.

2. The processor core clock frequency is derived from BCLK.
3. The period specified here is the average period. A given period may vary from this specification as governed by the period stability specification (T2).
4. For the clock jitter specification, refer to the *CK00 Clock Synthesizer/Driver Design Guidelines*.
5. In this context, period stability is defined as the worst case timing difference between successive crossover voltages. In other words, the largest absolute difference between adjacent clock periods must be less than the period stability.
6. Slew rate is measured between the 35% and 65% points of the clock swing (V_L and V_H).

Table 15. Front Side Bus Common Clock AC Specifications

T# Parameter	Min	Max	Unit	Figure	Notes ^{1, 2, 3}
T10: Common Clock Output Valid Delay	0.12	1.27	nS	9	4
T11: Common Clock Input Setup Time	0.65	N/A	nS	9	5
T12: Common Clock Input Hold Time	0.40	N/A	nS	9	5
T13: RESET# Pulse Width	1.00	10.00	mS	12	6, 7, 8

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. Not 100% tested. Specified by design characterization.
3. All common clock AC timings for AGTL+ signals are referenced to the Crossing Voltage (V_{CROSS}) of the BCLK[1:0] at rising edge of BCLK0. All common clock AGTL+ signal timings are referenced at GTLREF at the processor core.
4. Valid delay timings for these signals are specified into the test circuit described in [Figure 5](#) and with GTLREF at $2/3 * V_{CC} \pm 2\%$.
5. Specification is for a minimum swing defined between AGTL+ V_{IL_MAX} to V_{IH_MIN} . This assumes an edge rate of 0.3 V/nS to 4.0 V/nS.
6. RESET# can be asserted (active) asynchronously, but must be deasserted synchronously.
7. This should be measured after V_{CC} and BCLK[1:0] become stable.
8. Maximum specification applies only while PWRGOOD is asserted.

Table 16. Front Side Bus Source Synchronous AC Specifications (Page 1 of 2)

T# Parameter	Min	Max	Unit	Figure	Notes
T20: Source Sync. Output Valid Delay (first data/address only)	0.20	1.30	nS	10, 11	1, 2, 3, 4, 5
T21: T_{VBD} Source Sync. Data Output Valid Before Data Strobe	0.85		nS	11	1, 2, 3, 4, 5, 8
T22: T_{VAD} Source Sync. Data Output Valid After Data Strobe	0.85		nS	11	1, 2, 3, 4, 5, 8
T23: T_{VBA} Source Sync. Address Output Valid Before Address Strobe	1.88		nS	10	1, 2, 3, 4, 5, 8
T24: T_{VAA} Source Sync. Address Output Valid After Address Strobe	1.88		nS	10	1, 2, 3, 4, 5, 9
T25: T_{SUSS} Source Sync. Input Setup Time	0.21		nS	10, 11	1, 2, 3, 4, 6
T26: T_{HSS} Source Sync. Input Hold Time	0.21		nS	10, 11	1, 2, 3, 4, 6
T27: T_{SUCC} Source Sync. Input Setup Time to BCLK	0.65		nS	10, 11	1, 2, 3, 4, 7
T28: T_{FASS} First Address Strobe to Second Address Strobe		1/2	BCLKs	10	1, 2, 3, 4, 10, 14

Table 16. Front Side Bus Source Synchronous AC Specifications (Page 2 of 2)

T# Parameter	Min	Max	Unit	Figure	Notes
T29: T _{FDSS} : First Data Strobe to Subsequent Strobes		n/4	BCLKs	11	1, 2, 3, 4, 11, 12, 14
T30: Data Strobe 'n' (DSTBN#) Output Valid Delay	8.80	10.20	nS	11	1, 2, 3, 4, 13
T31: Address Strobe Output Valid Delay	2.27	4.23	nS	10	1, 2, 3, 4

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. Not 100% tested. Specified by design characterization.
3. All source synchronous AC timings are referenced to their associated strobe at GTLREF. Source synchronous data signals are referenced to the falling edge of their associated data strobe. Source synchronous address signals are referenced to the rising and falling edge of their associated address strobe. All source synchronous AGTL+ signal timings are referenced at GTLREF at the processor core.
4. Unless otherwise noted, these specifications apply to both data and address timings.
5. Valid delay timings for these signals are specified into the test circuit described in Figure 5 and with GTLREF at $2/3 * V_{CC} \pm 2\%$.
6. Specification is for a minimum swing defined between AGTL+ V_{IL_MAX} to V_{IH_MIN} . This assumes an edge rate of 0.3 V/nS to 4.0 V/nS.
7. All source synchronous signals must meet the specified setup time to BCLK as well as the setup time to each respective strobe.
8. This specification represents the minimum time the data or address will be valid before its strobe. Refer to the appropriate platform design guidelines for more information on the definitions and use of these specifications.
9. This specification represents the minimum time the data or address will be valid after its strobe. Refer to the appropriate platform design guidelines for more information on the definitions and use of these specifications.
10. The rising edge of ADSTB# must come approximately 1/2 BCLK period (5 nS) after the falling edge of ADSTB#.
11. For this timing parameter, n = 1, 2, and 3 for the second, third, and last data strobes respectively.
12. The second data strobe (the falling edge of DSTBn#) must come approximately 1/4 BCLK period (2.5 nS) after the first falling edge of DSTBp#. The third data strobe (the falling edge of DSTBp#) must come approximately 2/4 BCLK period (5 nS) after the first falling edge of DSTBp#. The last data strobe (the falling edge of DSTBn#) must come approximately 3/4 BCLK period (7.5 nS) after the first falling edge of DSTBp#.
13. This specification applies only to DSTBN[3:0]# and is measured to the second falling edge of the strobe.
14. This specification reflects a typical value, not a minimum or maximum..

Table 17. Miscellaneous Signals+ AC Specifications

T# Parameter	Min	Max	Unit	Figure	Notes
T35: Async GTL+ input pulse width	2	N/A	BCLKs		1, 2, 3, 4
T36: PWRGOOD to RESET# de-assertion time	1	10	mS	13	1, 2, 3, 4
T37: PWRGOOD inactive pulse width	10	N/A	BCLKs	13	1, 2, 3, 4, 5
T38: PROCHOT# pulse width	500		μS	15	1, 2, 3, 4, 6
T39: THERMTRIP# to Vcc Removal		0.5	S	16	

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. All AC timings for the Asynchronous GTL+ signals are referenced to the BCLK0 rising edge at Crossing Voltage (V_{CROSS}). All Asynchronous GTL+ signal timings are referenced at GTLREF.
3. These signals may be driven asynchronously.
4. Refer to Section 7.2 for additional timing requirements for entering and leaving low power states.
5. Refer to the PWRGOOD signal definition in Section 5.2 for more detail information on behavior of the signal.
6. Length of assertion for PROCHOT# does not equal internal clock modulation time. Time is allocated after the assertion of PROCHOT# for the processor to complete current instruction execution.

Table 18. Front Side Bus AC Specifications (Reset Conditions)

T# Parameter	Min	Max	Unit	Figure	Notes
T45: Reset Configuration Signals (A[31:3]#, BR[3:0]#, INIT#, SMI#) Setup Time	4		BCLKs	12	1
T46: Reset Configuration Signals (A[31:3]#, BR[3:0]#, INIT#, SMI#) Hold Time	2	20	BCLKs	12	2

1. Before the de-assertion of RESET#
2. After the clock that de-asserts RESET#.

Table 19. TAP Signal Group AC Specifications

T# Parameter	Min	Max	Unit	Figure	Notes 1,2,3,9
T55: TCK Period	60.0		nS	6	
T56: TCK Rise Time		9.5	nS	6	4
T57: TCK Fall Time		9.5	nS	6	4
T58: TMS, TDI Rise Time		8.5	nS	6	4
T59: TMS, TDI Fall Time		8.5	nS	6	4
T61: TDI, TMS Setup Time	0		nS	14	5, 7
T62: TDI, TMS Hold Time	3.0		nS	14	5, 7
T63: TDO Clock to Output Delay	0.5	3.5	nS	14	6
T64: TRST# Assert Time	2.0		T _{TCK}	15	8

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. Not 100% tested. Specified by design characterization.
3. All AC timings for the TAP signals are referenced to the TCK signal at 0.5 * V_{CC} at the processor pins. All TAP signal timings (TMS, TDI, etc) are referenced at the 0.5 * V_{CC} processor pins.
4. Rise and fall times are measured from the 20% to 80% points of the signal swing.
5. Referenced to the rising edge of TCK.
6. Referenced to the falling edge of TCK.
7. Specification for a minimum swing defined between TAP 20% to 80%. This assumes a minimum edge rate of 0.5 V/nS.
8. TRST# must be held asserted for 2 TCK periods to be guaranteed that it is recognized by the processor.
9. It is recommended that TMS be asserted while TRST# is being deasserted..

Table 20. SMBus Signal Group AC Specifications (Page 1 of 2)

T# Parameter	Min	Max	Unit	Figure	Notes
T70: SM_CLK Frequency	10	100	KHz		1, 2, 3
T71: SM_CLK Period	10	100	μS		1, 2, 3
T72: SM_CLK High Time	4.0	N/A	μS	17	1, 2, 3
T73: SM_CLK Low Time	4.7	N/A	μS	17	1, 2, 3
T74: SMBus Rise Time	0.02	1.0	μS	17	1, 2, 3, 5
T75: SMBus Fall Time	0.02	0.3	μS	17	1, 2, 3, 5
T76: SMBus Output Valid Delay	0.1	4.5	μS	18	1, 2, 3
T77: SMBus Input Setup Time	250	N/A	nS	17	1, 2, 3
T78: SMBus Input Hold Time	300	N/A	nS	17	1, 2, 3

Table 20. SMBus Signal Group AC Specifications (Page 2 of 2)

T# Parameter	Min	Max	Unit	Figure	Notes
T79: Bus Free Time	4.7	N/A	μS	17	1, 2, 3, 4, 6
T80: Hold Time after Repeated Start Condition	4.0	N/A	μS	17	1, 2, 3
T81: Repeated Start Condition Setup Time	4.7	N/A	μS	17	1, 2, 3
T82: Stop Condition Setup Time	4.0	N/A	μS	17	1, 2, 3

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. These parameters are based on design characterization and are not tested.
3. All AC timings for the SMBus signals are referenced at V_{IL_MAX} or V_{IL_MIN} and measured at the processor pins. Refer to Figure 17.
4. Minimum time allowed between request cycles.
5. Rise time is measured from ($V_{IL_MAX} - 0.15V$) to ($V_{IH_MIN} + 0.15V$). Fall time is measured from ($0.9 * SM_V_{CC}$) to ($V_{IL_MAX} - 0.15V$). DC parameters are specified in Table 11.
6. Following a write transaction, an internal device write cycle time of 10ms must be allowed before starting the next transaction.

2.14 Processor AC Timing Waveforms

The following figures are used in conjunction with the AC timing tables, Table 14 through Table 20.

Note: For Figure 6 through Figure 15, the following apply:

1. All common clock AC timings for AGTL+ signals are referenced to the Crossing Voltage (V_{CROSS}) of the BCLK[1:0] at rising edge of BCLK0. All common clock AGTL+ signal timings are referenced at GTLREF at the processor core (pads).
2. All source synchronous AC timings for AGTL+ signals are referenced to their associated strobe (address or data) at GTLREF. Source synchronous data signals are referenced to the falling edge of their associated data strobe. Source synchronous address signals are referenced to the rising and falling edge of their associated address strobe. All source synchronous AGTL+ signal timings are referenced at GTLREF at the processor core (pads).
3. All AC timings for AGTL+ strobe signals are referenced to BCLK[1:0] at V_{CROSS} . All AGTL+ strobe signal timings are referenced at GTLREF at the processor core (pads).
4. All AC Timing for the TAP signals are referenced to the TCK signal at $0.5 * V_{CC}$ at the processor pins. All TAP signal timings (TMS, TDI, etc.) are referenced at the $0.5 * V_{CC}$ at the processor core (pads).
5. All AC timings for the SMBus signals are referenced to the SM_CLK signal at $0.5 * SM_V_{CC}$ at the processor pins. All SMBus signal timings (SM_DAT, SM_ALERT#, etc.) are referenced at V_{IL_MAX} or V_{IL_MIN} at the processor pins.

3.0 Front Side Bus Signal Quality Specifications

This section documents signal quality metrics used to derive topology and routing guidelines through simulation. All specifications are made at the processor core (pad measurements).

Source synchronous data transfer requires the clean reception of data signals and their associated strobes. Ringing below receiver thresholds, non-monotonic signal edges, and excessive voltage swing will adversely affect system timings. Ringback and signal non-monotonicity cannot be tolerated since these phenomena may inadvertently advance receiver state machines. Excessive signal swings (overshoot and undershoot) are detrimental to silicon gate oxide integrity, and can cause device failure if absolute voltage limits are exceeded. Additionally, overshoot and undershoot can degrade timing due to the build up of inter-symbol interference (ISI) effects. For these reasons, it is crucial that the designer assure acceptable signal quality across all systematic variations encountered in volume manufacturing.

Specifications for signal quality are for measurements at the processor core only and are only observable through simulation. The same is true for all front side bus AC timing specifications in [Section 2.13](#). Therefore, proper simulation of the processor front side bus is the only means to verify proper timing and signal quality metrics.

3.1 Front Side Bus Clock (BCLK) Signal Quality Specifications and Measurement Guidelines

[Table 21](#) describes the signal quality specifications at the processor pads for the processor front side bus clock (BCLK) signals. [Figure 20](#) describes the signal quality waveform for the front side bus clock at the processor pads.

Table 21. BCLK Signal Quality Specifications

Parameter	Min	Max	Unit	Figure	Notes
BCLK[1:0] Overshoot	N/A	0.30	V	20	1
BCLK[1:0] Undershoot	N/A	0.30	V	20	1
BCLK[1:0] Ringback Margin	0.20	N/A	V	20	1
BCLK[1:0] Threshold Region	N/A	0.10	V	20	1, 2

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
2. The rising and falling edge ringback voltage specified is the minimum (rising) or maximum (falling) absolute voltage the BCLK signal can dip back to after passing the V_{IH} (rising) or V_{IL} (falling) voltage limits. This specification is an absolute value.

Figure 20. BCLK[1:0] Signal Integrity Waveform

3.2 Front Side Bus Signal Quality Specifications and Measurement Guidelines

Many scenarios have been simulated to generate a set of AGTL+ layout guidelines which are available in the appropriate platform design guidelines.

Table 22 provides the signal quality specifications for all processor signals for use in simulating signal quality at the processor pads.

Maximum allowable overshoot and undershoot specifications for a given duration of time are detailed in Table 24 through Table 27. Figure 21 shows the front side bus ringback tolerance for low-to-high transitions and Figure 22 shows ringback tolerance for high-to-low transitions.

Table 22. Ringback Specifications for AGTL+ and Asynchronous GTL+ Buffers

Signal Group	Transition	Maximum Ringback (with Input Diodes Present)	Unit	Figure	Notes
AGTL+, Asynch GTL+	L → H	$GTLREF + 0.100 \cdot GTLREF$	V	21	1, 2, 3, 4, 5, 6, 7
AGTL+, Asynch GTL+	H → L	$GTLREF - 0.100 \cdot GTLREF$	V	22	1, 2, 3, 4, 5, 6, 7

NOTES:

1. All signal integrity specifications are measured at the processor core (pads).
2. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
3. Specifications are for the edge rate of 0.3 - 4.0 V/nS at the receiver.
4. All values specified by design characterization.
5. Please see Section 3.0 for maximum allowable overshoot.
6. Ringback between $GTLREF + 100$ mV and $GTLREF - 100$ mV is not supported.
7. Intel recommends simulations not exceed a ringback value of $GTLREF \pm 200$ mV to allow margin for other sources of system noise

Table 23. Ringback Specifications for TAP Buffers

Signal Group	Transition	Maximum Ringback (with Input Diodes Present)	Threshold	Unit	Figure	Notes
TAP and PWRGOO D	L → H	$V_{T+(max)}$ TO $V_{T-(max)}$	$V_{T+(max)}$	V	23	1, 2, 3, 4, 5
TAP and PWRGOO D	H → L	$V_{T-(min)}$ TO $V_{T+(min)}$	$V_{T-(min)}$	V	24	1, 2, 3, 4, 5

NOTES:

1. All signal integrity specifications are measured at the processor core (pads).
2. Unless otherwise noted, all specifications in this table apply to all processor frequencies and cache sizes.
3. Specifications are for the edge rate of 0.3 - 4.0 V/nS.
4. All values specified by design characterization.
5. Please see section 3.3 for maximum allowable overshoot.

Figure 21. Low-to-High Front Side Bus Receiver Ringback Tolerance for AGTL+ and Asynchronous GTL+ Buffers

Figure 22. High-to-Low Front Side Bus Receiver Ringback Tolerance for AGTL+ and Asynchronous GTL+ Buffers

Figure 24. High-to-Low Front Side Bus Receiver Ringback Tolerance for PWRGOOD and TAP Buffers

3.3 Front Side Bus Signal Quality Specifications and Measurement Guidelines

3.3.1 Overshoot/Undershoot Guidelines

Overshoot (or undershoot) is the absolute value of the maximum voltage above or below V_{SS} . The overshoot/undershoot specifications limit transitions beyond V_{CC} or V_{SS} due to the fast signal edge rates. The processor can be damaged by single and/or repeated overshoot or undershoot events on any input, output, or I/O buffer if the charge is large enough (i.e., if the over/undershoot is great enough). Determining the impact of an overshoot/undershoot condition requires knowledge of the magnitude, the pulse direction, and the activity factor (AF). Permanent damage to the processor is the likely result of excessive overshoot/undershoot.

When performing simulations to determine impact of overshoot and undershoot, ESD diodes must be properly characterized. ESD protection diodes do not act as voltage clamps and will not provide overshoot or undershoot protection. ESD diodes modeled within Intel's signal integrity models do not clamp undershoot or overshoot and will yield correct simulation results. If other signal integrity models are being used to characterize the processor front side bus, care must be taken to ensure that ESD models do not clamp extreme voltage levels. Intel's signal integrity models also contain I/O capacitance characterization. Therefore, removing the ESD diodes from a signal integrity model will impact results and may yield excessive overshoot/undershoot.

3.3.2 Overshoot/Undershoot Magnitude

Magnitude describes the maximum potential difference between a signal and its voltage reference level (V_{SS}). It is important to note that overshoot and undershoot conditions are separate and their impact must be determined independently.

Overshoot/undershoot magnitude levels must observe the absolute maximum specifications listed in [Table 24](#) through [Table 27](#). These specifications must not be violated at any time regardless of bus activity or system state. Within these specifications are threshold levels that define different allowed pulse duration. Provided that the magnitude of the overshoot/undershoot is within the absolute maximum specifications, the pulse magnitude, duration and activity factor must all be used to determine if the overshoot/undershoot pulse is within specifications.

3.3.3 Overshoot/Undershoot Pulse Duration

Pulse duration describes the total time an overshoot/undershoot event exceeds the overshoot/undershoot reference voltage (V_{CC}). The total time could encompass several oscillations above the reference voltage. Multiple overshoot/undershoot pulses within a single overshoot/undershoot event may need to be measured to determine the total pulse duration.

Note 1: Oscillations below the reference voltage can not be subtracted from the total overshoot/undershoot pulse duration.

3.3.4 Activity Factor

Activity Factor (AF) describes the frequency of overshoot (or undershoot) occurrence relative to a clock. Since the highest frequency of assertion of any common clock signal is every other clock, an $AF = 1$ indicates that the specific overshoot (or undershoot) waveform occurs every other clock cycle. Thus, an $AF = 0.01$ indicates that the specific overshoot (or undershoot) waveform occurs one time in every 200 clock cycles.

For source synchronous signals (address, data, and associated strobes), the activity factor is in reference to the strobe edge. The highest frequency of assertion of any source synchronous signal is every active edge of its associated strobe. So, an $AF = 1$ indicates that the specific overshoot (or undershoot) waveform occurs every strobe cycle.

The specifications provided in Table 24 through Table 27 show the maximum pulse duration allowed for a given overshoot/undershoot magnitude at a specific activity factor. Each table entry is independent of all others, meaning that the pulse duration reflects the existence of overshoot/undershoot events of that magnitude ONLY. A platform with an overshoot/undershoot that just meets the pulse duration for a specific magnitude where the $AF < 1$, means that there can be no other overshoot/undershoot events, even of lesser magnitude (note that if $AF = 1$, then the event occurs at all times and no other events can occur).

NOTE:

1. Activity factor for common clock AGTL+ signals is referenced to BCLK[1:0] frequency.
2. Activity factor for source synchronous (2x) signals is referenced to ADSTB[1:0]#.
3. Activity factor for source synchronous (4x) signals is referenced to DSTBP[3:0]# and DSTBN[3:0]#.

3.3.5 Reading Overshoot/Undershoot Specification Tables

The processor overshoot/undershoot specification is not a simple single value. Instead, many factors are needed to determine what the overshoot/undershoot specification is. In addition to the magnitude of the overshoot, the following parameters must also be known: the width of the overshoot and the activity factor (AF). To determine the allowed overshoot for a particular overshoot event, the following must be done:

1. Determine the *signal group* that particular signal falls into. For AGTL+ signals operating in the 4X source synchronous domain, Table 24 should be used. For AGTL+ signals operating in the 2X source synchronous domain, Table 25 should be used. If the signal is an AGTL+ signal operating in the common clock domain, Table 26 should be used. Finally, for all other signals residing in the 33 MHz domain (asynchronous GTL+, TAP, etc.), Table 27 should be used.
2. Determine the *magnitude* of the overshoot or the undershoot (relative to V_{SS}).
3. Determine the *activity factor* (how often does this overshoot occurs).
4. Next, from the appropriate specification table, determine the *maximum pulse duration* (in nanoseconds) allowed.
5. Compare the specified maximum pulse duration to the signal being measured. If the pulse duration measured is less than the pulse duration shown in the table, then the signal meets the specifications.

Undershoot events must be analyzed separately from overshoot events as they are mutually exclusive.

3.3.6 Determining if a System Meets the Overshoot/Undershoot Specifications

The overshoot/undershoot specifications listed in the following tables specify the allowable overshoot/undershoot for a single overshoot/undershoot event. However most systems will have multiple overshoot and/or undershoot events that each have their own set of parameters (duration, AF and magnitude). While each overshoot on its own may meet the overshoot specification, when the total impact of all overshoot events are considered, the system may fail. A guideline to ensure a system passes the overshoot and undershoot specifications is shown below:

- Ensure that no signal ever exceeds V_{CC} or -0.25 V OR
- If only one overshoot/undershoot event magnitude occurs, ensure it meets the overshoot/undershoot specifications in the following tables OR
- If multiple overshoots and/or multiple undershoots occur, measure the worst case pulse duration for each magnitude and compare the results against the $AF = 1$ specifications. If all of these worst case overshoot or undershoot events meet the specifications (measured time < specifications) in the table (where $AF=1$), then the system passes.

The following notes apply to [Table 24](#) through [Table 27](#):

- Absolute Maximum Overshoot magnitude of 1.8V must never be exceeded.
- Absolute Maximum Overshoot is measured referenced to V_{SS} , Pulse Duration of overshoot is measured relative to V_{CC} .
- Absolute Maximum Undershoot and Pulse Duration of undershoot is measured relative to V_{SS} .
- Ringback below V_{CC} cannot be subtracted from overshoots/undershoots.
- Lesser undershoot does not allocate longer or larger overshoot.
- System designers are strongly encouraged to follow Intel's layout guidelines.
- All values specified by design characterization.

Table 24. Source Synchronous (400 MHz) AGTL+ Signal Group Overshoot/Undershoot Tolerance

Absolute Maximum Overshoot (V)	Absolute Maximum Undershoot (V)	Pulse Duration (ns) AF = 1	Pulse Duration (ns) AF = 0.1	Pulse Duration (ns) AF = 0.01
1.80	- 0.320	0.01	0.15	1.58
1.75	- 0.270	0.03	0.45	4.60
1.70	- 0.220	0.09	1.28	5.00
1.65	- 0.170	0.25	3.71	5.00
1.60	- 0.120	0.76	5.00	5.00
1.55	- 0.070	2.54	5.00	5.00

NOTES:

1. These specifications are measured at the processor pad.
2. Assumes a BCLK period of 10 nS.
3. AF is referenced to associated source synchronous strobes.

Table 25. Source Synchronous (200 MHz) AGTL+ Signal Group Overshoot/Undershoot Tolerance

Absolute Maximum Overshoot (V)	Absolute Maximum Undershoot (V)	Pulse Duration (ns) AF = 1	Pulse Duration (ns) AF = 0.1	Pulse Duration (ns) AF = 0.01
1.80	- 0.320	0.03	0.29	2.88
1.75	- 0.270	0.06	0.62	6.25
1.70	- 0.220	0.18	1.75	10.00
1.65	- 0.170	0.51	5.06	10.00
1.60	- 0.120	1.52	10.00	10.00
1.55	- 0.07	5.08	10.00	10.00

NOTES:

1. These specifications are measured at the processor pad.
2. Assumes a BCLK period of 10 ns.
3. AF is referenced to associated source synchronous strobes.

Table 26. Common Clock (100 MHz) AGTL+ Signal Group Overshoot/Undershoot Tolerance

Absolute Maximum Overshoot (V)	Absolute Maximum Undershoot (V)	Pulse Duration (ns) AF = 1	Pulse Duration (ns) AF = 0.1	Pulse Duration (ns) AF = 0.01
1.80	- 0.320	0.06	0.58	5.77
1.75	- 0.270	0.12	1.25	12.49
1.70	- 0.220	0.35	3.50	20.00
1.65	- 0.170	1.01	10.12	20.00
1.60	- 0.120	3.04	20.00	20.00
1.55	- 0.07	10.16	20.00	20.00

NOTES:

1. These specifications are measured at the processor pad.
2. BCLK period is 10 nS.
3. WIRED OR processor signals can tolerate upto 1 V of overshoot/undershoot.
4. AF is referenced to BCLK[1:0].

Table 27. Asynchronous GTL+, PWRGOOD, and TAP Signal Groups Overshoot/Undershoot Tolerance

Absolute Maximum Overshoot (V)	Absolute Maximum Undershoot (V)	Pulse Duration (ns) AF = 1	Pulse Duration (ns) AF = 0.1	Pulse Duration (ns) AF = 0.01
1.80	- 0.320	0.17	1.73	17.30
1.75	- 0.270	0.37	3.75	37.48
1.70	- 0.220	1.05	10.51	60.00
1.65	- 0.170	3.04	30.37	60.00
1.60	- 0.120	9.13	60.00	60.00
1.55	- 0.07	30.48	60.00	60.00

NOTES:

1. These specifications are measured at the processor pad.
2. These signals are assumed in a 33 MHz time domain.

Figure 25. Maximum Acceptable Overshoot/Undershoot Waveform

4.0 Mechanical Specifications

The Intel® Xeon™ processor with 512 KB L2 cache uses Interposer Micro Pin Grid Array (INT-mPGA) package technology. Components of the package include a flip-chip ball grid array (FC-BGA) package containing the processor die covered by an integrated heat spreader (IHS) mounted to a pinned FR4 interposer. Mechanical specifications for the processor are given in this section. See [Section 1.1](#) for terminology definitions. [Figure 26](#) provides a basic assembly drawing and includes the components which make up the entire processor. In addition to the package components, several components are located on the FR4 interposer, including an EEPROM and a thermal sensor. Package dimensions are provided in [Table 28](#).

The Intel® Xeon™ processor with 512 KB L2 cache utilizes a surface mount 603-pin zero-insertion force (ZIF) socket for installation into the baseboard. See the *603-Pin Socket Design Guidelines* for further details on the processor socket.

For [Figure 28](#) through [Figure 32](#), the following notes apply:

1. Unless otherwise specified, the following drawings are dimensioned in millimeters.
2. All dimensions are not tested, but are guaranteed by design characterization.
3. Figures and drawings labelled as “Reference Dimensions” are provided for informational purposes only. Reference Dimensions are extracted from the mechanical design database and are nominal dimensions with no tolerance information applied. Reference Dimensions are NOT checked as part of the processor manufacturing process. Unless noted as such, dimensions in parentheses without tolerances are Reference Dimensions.
4. Drawings are not to scale.

Figure 26. INT-mPGA Processor Package Assembly Drawing (Includes Socket)

Note: This drawing is not to scale and is for reference only. The 603-pin socket is supplied as a reference only.

1. Integrated Heat Spreader (IHS)
2. Thermal Interface Material (TIM) between processor die and IHS
3. Processor die
4. Flip Chip interconnect
5. FCBGA (Flip Chip Ball Grid Array) package
6. FCBGA solder joints
7. Processor interposer
8. 603-pin socket

Figure 29 details the keep-in zone for components mounted to the top side of the processor interposer. The components include the EEPROM, thermal sensor, resistors and capacitors.

Figure 29. INT-mPGA Processor Package Top View: Component Height Keep-in

Figure 30 details the keep-in specification for pin-side components. The processor may contain pin side capacitors mounted to the processor package. These capacitors will be exposed within the opening of the interposer cavity.

Figure 30. INT-mPGA Processor Package Cross Section View: Pin Side Component Keep-in

Figure 31. INT-mPGA Processor Package: Pin Detail

1. Kovar pin with plating of 0.2 micrometers Au over 2.0 micrometer Ni.
2. 0.254 Diametric true position, pin to pin.

Figure 32 details the flatness and tilt specifications for the IHS of the Intel Xeon processor, respectively. Tilt is measured with the reference datum set to the bottom of the processor interposer.

Figure 32. IHS Flatness and Tilt Drawing

4.2 Processor Package Load Specifications

Table 29 provides dynamic and static load specifications for the processor IHS. These mechanical load limits should not be exceeded during heat sink assembly, mechanical stress testing, or standard drop and shipping conditions. The heat sink attach solutions must not induce continuous stress onto the processor with the exception of a uniform load to maintain the heat sink-to-processor thermal interface. It is not recommended to use any portion of the processor interposer as a mechanical reference or load bearing surface for thermal solutions.

Table 29. Package Dynamic and Static Load Specifications

Parameter	Max	Unit	Unit
Static	50	lbf	1, 2, 3
Dynamic	$50 + 1 \text{ lb} * 50\text{G input} * 1.8 \text{ (AF)}$ = 140	lbf	1, 2, 4, 5

NOTES:

1. This specification applies to a uniform compressed load.
2. This is the maximum static force that can be applied by the heatsink and clip to maintain the heatsink and processor interface.
3. These parameters are based on design characterization and not tested.
4. Dynamic loading specifications are defined assuming a maximum duration of 11ms.
5. The heatsink weight is assumed to be one pound. Shock input to the system during shock testing is assumed to be 50 G's. AF is the amplification factor.

4.3 Insertion Specifications

The processor can be inserted and removed 15 times from a 603-pin socket meeting the *603-Pin Socket Design Guidelines* document. Note that this specification is based on design characterization and is not tested.

4.4 Mass Specifications

Table 30 specifies the processors mass. This includes all components which make up the entire processor product.

Table 30. Processor Mass

Processor	Mass (grams)
Intel® Xeon™ processor with 512 KB L2 cache	25

4.5 Materials

The processor is assembled from several components. The basic material properties are described in Table 31.

Table 31. Processor Material Properties

Component	Material
Integrated Heat Spreader	Nickel plated copper
FC-BGA	BT Resin
Interposer	FR4
Interposer pins	Kovar with Gold over nickel

4.6 Markings

The following section details the processor top-side laser markings. It is provided to aid in the identification of the processor.

Figure 33. Processor Top-Side Markings

NOTE:

1. Character size for laser markings is: height 0.050" (1.27mm), width 0.032" (0.81mm).
2. All characters will be in upper case.

Figure 34. Processor Bottom-Side Markings

4.7 Pin-Out Diagram

This section provides two view of the processor pin grid. [Figure 35](#) and [Figure 36](#) detail the coordinates of the processor pins.

Figure 35. Processor Pin Out Diagram: Top View

1. These are "Reserved" pins on the Intel Xeon processor. In systems utilizing the Intel Xeon processor, the system designer must terminate these signals to the processor V_{CC} .
2. Baseboard treating AA3 and AB3 as Reserved will operate correctly with a bus clock of 100 MHz.

1. These are "Reserved" pins on the Intel Xeon processor. In systems utilizing the Intel Xeon processor, the system designer must terminate these signals to the processor V_{CC}.
2. Baseboards treating AA3 and AB3 as Reserved will operate correctly with a bus clock of 100 MHz.

5.2 Signal Definitions

Table 41. Signal Definitions (Page 1 of 10)

Name	Type	Description	Notes												
A[35:3]#	I/O	A[35:3]# (Address) define a 2^{36} byte physical memory address space. In sub-phase 1 of the address phase, these pins transmit the address of a transaction. In sub-phase 2, these pins transmit transaction type information. These signals must connect the appropriate pins of all agents on the front side bus. A[35:3]# are protected by parity signals AP[1:0]#. A[35:3]# are source synchronous signals and are latched into the receiving buffers by ADSTB[1:0]#. On the active-to-inactive transition of RESET#, the processors sample a subset of the A[35:3]# pins to determine their power-on configuration. See Section 7.1.	4												
A20M#	I	If A20M# (Address-20 Mask) is asserted, the processor masks physical address bit 20 (A20#) before looking up a line in any internal cache and before driving a read/write transaction on the bus. Asserting A20M# emulates the 8086 processor's address wrap-around at the 1 MByte boundary. Assertion of A20M# is only supported in real mode. A20M# is an asynchronous signal. However, to ensure recognition of this signal following an I/O write instruction, it must be valid along with the TRDY# assertion of the corresponding I/O write bus transaction.	3												
ADS#	I/O	ADS# (Address Strobe) is asserted to indicate the validity of the transaction address on the A[35:3]# pins. All bus agents observe the ADS# activation to begin parity checking, protocol checking, address decode, internal snoop, or deferred reply ID match operations associated with the new transaction. This signal must connect the appropriate pins on all front side bus agents.	4												
ADSTB[1:0]#	I/O	Address strobes are used to latch A[35:3]# and REQ[4:0]# on their rising and falling edge.	4												
AP[1:0]#	I/O	AP[1:0]# (Address Parity) are driven by the request initiator along with ADS#, A[35:3]#, and the transaction type on the REQ[4:0]# pins. A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. This allows parity to be high when all the covered signals are high. AP[1:0]# should connect the appropriate pins of all front side bus agents. The following table defines the coverage model of these signals. <table><tr><th>Request Signals</th><th>Subphase 1</th><th>Subphase 2</th></tr><tr><td>A[35:24]#</td><td>AP0#</td><td>AP1#</td></tr><tr><td>A[23:3]#</td><td>AP1#</td><td>AP0#</td></tr><tr><td>REQ[4:0]#</td><td>AP1#</td><td>AP0#</td></tr></table>	Request Signals	Subphase 1	Subphase 2	A[35:24]#	AP0#	AP1#	A[23:3]#	AP1#	AP0#	REQ[4:0]#	AP1#	AP0#	4
Request Signals	Subphase 1	Subphase 2													
A[35:24]#	AP0#	AP1#													
A[23:3]#	AP1#	AP0#													
REQ[4:0]#	AP1#	AP0#													
BCLK[1:0]	I	The differential pair BCLK (Bus Clock) determines the bus frequency. All processor front side bus agents must receive these signals to drive their outputs and latch their inputs. All external timing parameters are specified with respect to the rising edge of BCLK0 crossing the falling edge of BCLK1.	4												

Table 41. Signal Definitions (Page 2 of 10)

Name	Type	Description	Notes
BINIT#	I/O	BINIT# (Bus Initialization) may be observed and driven by all processor front side bus agents and if used, must connect the appropriate pins of all such agents. If the BINIT# driver is enabled during power on configuration, BINIT# is asserted to signal any bus condition that prevents reliable future information. If BINIT# observation is enabled during power-on configuration (see Section 7.1) and BINIT# is sampled asserted, symmetric agents reset their bus LOCK# activity and bus request arbitration state machines. The bus agents do not reset their IOQ and transaction tracking state machines upon observation of BINIT# assertion. Once the BINIT# assertion has been observed, the bus agents will re-arbitrate for the front side bus and attempt completion of their bus queue and IOQ entries. If BINIT# observation is disabled during power-on configuration, a central agent may handle an assertion of BINIT# as appropriate to the error handling architecture of the system.	4
BNR#	I/O	BNR# (Block Next Request) is used to assert a bus stall by any bus agent who is unable to accept new bus transactions. During a bus stall, the current bus owner cannot issue any new transactions. Since multiple agents might need to request a bus stall at the same time, BNR# is a wire-OR signal which must connect the appropriate pins of all processor front side bus agents. In order to avoid wire-OR glitches associated with simultaneous edge transitions driven by multiple drivers, BNR# is activated on specific clock edges and sampled on specific clock edges.	4
BPM[5:0]#	I/O	BPM[5:0]# (Breakpoint Monitor) are breakpoint and performance monitor signals. They are outputs from the processor which indicate the status of breakpoints and programmable counters used for monitoring processor performance. BPM[5:0]# should connect the appropriate pins of all front side bus agents. BPM4# provides PRDY# (Probe Ready) functionality for the TAP port. PRDY# is a processor output used by debug tools to determine processor debug readiness. BPM5# provides PREQ# (Probe Request) functionality for the TAP port. PREQ# is used by debug tools to request debug operation of the processors. BPM[5:4]# must be bussed to all bus agents. These signals do not have on-die termination and must be terminated at the end agent. See the appropriate platform design guidelines for additional information.	3
BPRI#	I	BPRI# (Bus Priority Request) is used to arbitrate for ownership of the processor front side bus. It must connect the appropriate pins of all processor front side bus agents. Observing BPRI# active (as asserted by the priority agent) causes all other agents to stop issuing new requests, unless such requests are part of an ongoing locked operation. The priority agent keeps BPRI# asserted until all of its requests are completed, then releases the bus by deasserting BPRI#.	4

Table 41. Signal Definitions (Page 3 of 10)

Name	Type	Description	Notes															
BR0# BR[1:3]# ¹	I/O I	BR[3:0]# (Bus Request) drive the BREQ[3:0]# signals in the system. The BREQ[3:0]# signals are interconnected in a rotating manner to individual processor pins. BR2# and BR3# must not be utilized in a dual processor platform design. The table below gives the rotating interconnect between the processor and bus signals for dual processor systems. BR[1:0]# Signals Rotating Interconnect, dual processor system <table><tr><th>Bus Signal</th><th>Agent 0 Pins</th><th>Agent 1 Pins</th></tr><tr><td>BREQ0#</td><td>BR0#</td><td>BR1#</td></tr><tr><td>BREQ1#</td><td>BR1#</td><td>BR0#</td></tr></table> During power-up configuration, the central agent must assert the BR0# bus signal. All symmetric agents sample their BR[1:0]# pins on active-to-inactive transition of RESET#. The pin on which the agent samples an active level determines its agent ID. All agents then configure their pins to match the appropriate bus signal protocol as shown below. BR[1:0]# Signal Agent IDs <table><tr><th>BR[1:0]# Signals Rotating Interconnect, dual processor system</th><th>Agent ID</th></tr><tr><td>BR0#</td><td>0</td></tr><tr><td>BR1#</td><td>1</td></tr></table> During power-on configuration, the central agent must assert the BR0# bus signal. All symmetric agents sample their BR[3:0]# pins on the active-to-inactive transition of RESET#. The pin which the agent samples asserted determines its agent ID. These signals do not have on-die termination and must be terminated at the end agent. See the appropriate platform design guidelines for additional information.	Bus Signal	Agent 0 Pins	Agent 1 Pins	BREQ0#	BR0#	BR1#	BREQ1#	BR1#	BR0#	BR[1:0]# Signals Rotating Interconnect, dual processor system	Agent ID	BR0#	0	BR1#	1	1,4

BREQ1#	BR1#	BR0#																
BR[1:0]# Signals Rotating Interconnect, dual processor system	Agent ID																	
BR0#	0																	
BR1#	1																	
BSEL[1:0]	O	These output signals are used to select the front side bus frequency. A BSEL[1:0] = "00" will select a 100 MHz bus clock frequency. The frequency is determined by the processor(s), chipset, and frequency synthesizer capabilities. All front side bus agents must operate at the same frequency. Individual processors will only operate at their specified front side bus (FSB) frequency. On baseboards which support operation only at 100 MHz bus clocks these signals can be ignored. On baseboards employing the use of these signals, a 1 KΩ pull-up resistor be used. See Table 2 "Front Side Bus Clock Frequency Select Truth Table for BSEL[1:0]" on page 17 for output values.																
COMP[1:0]	I	COMP[1:0] must be terminated to V_{SS} on the baseboard using precision resistors. These inputs configure the AGTL+ drivers of the processor. Refer to the appropriate platform design guidelines and Table 13 for implementation details.																

Table 41. Signal Definitions (Page 4 of 10)

Name	Type	Description	Notes															
D[63:0]#	I/O	D[63:0]# (Data) are the data signals. These signals provide a 64-bit data path between the processor front side bus agents, and must connect the appropriate pins on all such agents. The data driver asserts DRDY# to indicate a valid data transfer. D[63:0]# are quad-pumped signals, and will thus be driven four times in a common clock period. D[63:0]# are latched off the falling edge of both DSTBP[3:0]# and DSTBN[3:0]#. Each group of 16 data signals correspond to a pair of one DSTBP# and one DSTBN#. The following table shows the grouping of data signals to strobes and DBI#. <table><tr><th>Data Group</th><th>DSTBN/ DSTBP</th><th>DBI#</th></tr><tr><td>D[15:0]#</td><td>0</td><td>0</td></tr><tr><td>D[31:16]#</td><td>1</td><td>1</td></tr><tr><td>D[47:32]#</td><td>2</td><td>2</td></tr><tr><td>D[63:48]#</td><td>3</td><td>3</td></tr></table> Furthermore, the DBI# pins determine the polarity of the data signals. Each group of 16 data signals corresponds to one DBI# signal. When the DBI# signal is active, the corresponding data group is inverted and therefore sampled active high.	Data Group	DSTBN/ DSTBP	DBI#	D[15:0]#	0	0	D[31:16]#	1	1	D[47:32]#	2	2	D[63:48]#	3	3	4
Data Group	DSTBN/ DSTBP	DBI#																
D[15:0]#	0	0																
D[31:16]#	1	1																
D[47:32]#	2	2																
D[63:48]#	3	3																
DBI[3:0]#	I/O	DBI[3:0]# are source synchronous and indicate the polarity of the D[63:0]# signals. The DBI[3:0]# signals are activated when the data on the data bus is inverted. The bus agent will invert the data bus signals if more than half the bits, within a 16-bit group, change logic level in the next cycle. DBI[3:0] Assignment To Data Bus <table><tr><th>Bus Signal</th><th>Data Bus Signals</th></tr><tr><td>DBI0#</td><td>D[15:0]#</td></tr><tr><td>DBI1#</td><td>D[31:16]#</td></tr><tr><td>DBI2#</td><td>D[47:32]#</td></tr><tr><td>DBI3#</td><td>D[63:48]#</td></tr></table>	Bus Signal	Data Bus Signals	DBI0#	D[15:0]#	DBI1#	D[31:16]#	DBI2#	D[47:32]#	DBI3#	D[63:48]#	4					
Bus Signal	Data Bus Signals																	
DBI0#	D[15:0]#																	
DBI1#	D[31:16]#																	
DBI2#	D[47:32]#																	
DBI3#	D[63:48]#																	
DBSY#	I/O	DBSY# (Data Bus Busy) is asserted by the agent responsible for driving data on the processor front side bus to indicate that the data bus is in use. The data bus is released after DBSY# is deasserted. This signal must connect the appropriate pins on all processor front side bus agents.	4															
DEFER#	I	DEFER# is asserted by an agent to indicate that a transaction cannot be guaranteed in-order completion. Assertion of DEFER# is normally the responsibility of the addressed memory or I/O agent. This signal must connect the appropriate pins of all processor front side bus agents.	4															
DP[3:0]#	I/O	DP[3:0]# (Data Parity) provide parity protection for the D[63:0]# signals. They are driven by the agent responsible for driving D[63:0]#, and must connect the appropriate pins of all processor front side bus agents.	4															
DRDY#	I/O	DRDY# (Data Ready) is asserted by the data driver on each data transfer, indicating valid data on the data bus. In a multi-common clock data transfer, DRDY# may be deasserted to insert idle clocks. This signal must connect the appropriate pins of all processor front side bus agents.	4															
DSTBN[3:0]#	I/O	Data strobe used to latch in D[63:0]#.	4															
DSTBP[3:0]#	I/O	Data strobe used to latch in D[63:0]#.	4															

Table 41. Signal Definitions (Page 5 of 10)

Name	Type	Description	Notes
FERR#/PBE#	O	FERR#/PBE# (floating point error/pending break event) is a multiplexed signal and its meaning is qualified by STPCLK#. When STPCLK# is not asserted, FERR#/PBE# indicates a floating-point error and will be asserted when the processor detects an unmasked floating-point error. When STPCLK# is not asserted, FERR#/PBE# is similar to the ERROR# signal on the Intel 387 coprocessor, and is included for compatibility with systems using MS-DOS*-type floating-point error reporting. When STPCLK# is asserted, an assertion of FERR#/PBE# indicates that the processor has a pending break event waiting for service. The assertion of FERR#/PBE# indicates that the processor should be returned to the Normal state. For additional information on the pending break event functionality, including the identification of support of the feature and enable/disable information, refer to volume 3 of the Intel Architecture Software Developer's Manual and the Intel Processor Identification and the CPUID Instruction application note. This signal does not have on-die termination and must be terminated at the end agent. See the appropriate Platform Design Guideline for additional information.	3
GTLREF	I	GTLREF determines the signal reference level for AGTL+ input pins. GTLREF should be set at 2/3Vcc. GTLREF is used by the AGTL+ receivers to determine if a signal is a logical 0 or a logical 1.	
HIT# HITM#	I/O I/O	HIT# (Snoop Hit) and HITM# (Hit Modified) convey transaction snoop operation results. Any front side bus agent may assert both HIT# and HITM# together to indicate that it requires a snoop stall, which can be continued by reasserting HIT# and HITM# together. Since multiple agents may deliver snoop results at the same time, HIT# and HITM# are wire-OR signals which must connect the appropriate pins of all processor front side bus agents. In order to avoid wire-OR glitches associated with simultaneous edge transitions driven by multiple drivers, HIT# and HITM# are activated on specific clock edges and sampled on specific clock edges.	4
IERR#	O	IERR# (Internal Error) is asserted by a processor as the result of an internal error. Assertion of IERR# is usually accompanied by a SHUTDOWN transaction on the processor front side bus. This transaction may optionally be converted to an external error signal (e.g., NMI) by system core logic. The processor will keep IERR# asserted until the assertion of RESET#, BINIT#, or INIT#. This signal does not have on-die termination and must be terminated at the end agent. See the appropriate Platform Design Guideline for additional information.	3
IGNNE#	I	IGNNE# (Ignore Numeric Error) is asserted to force the processor to ignore a numeric error and continue to execute noncontrol floating-point instructions. If IGNNE# is deasserted, the processor generates an exception on a noncontrol floating-point instruction if a previous floating-point instruction caused an error. IGNNE# has no effect when the NE bit in control register 0 (CRO) is set. IGNNE# is an asynchronous signal. However, to ensure recognition of this signal following an I/O write instruction, it must be valid along with the TRDY# assertion of the corresponding I/O write bus transaction.	3
INIT#	I	INIT# (Initialization), when asserted, resets integer registers inside all processors without affecting their internal caches or floating-point registers. Each processor then begins execution at the power-on Reset vector configured during power-on configuration. The processor continues to handle snoop requests during INIT# assertion. INIT# is an asynchronous signal and must connect the appropriate pins of all processor front side bus agents. If INIT# is sampled active on the active to inactive transition of RESET#, then the processor executes its Built-in Self-Test (BIST).	3

Table 41. Signal Definitions (Page 6 of 10)

Name	Type	Description	Notes
LINT[1:0]	I	LINT[1:0] (Local APIC Interrupt) must connect the appropriate pins of all front side bus agents. When the APIC functionality is disabled, the LINT0 signal becomes INTR, a maskable interrupt request signal, and LINT1 becomes NMI, a nonmaskable interrupt. INTR and NMI are backward compatible with the signals of those names on the Pentium processor. Both signals are asynchronous. Both of these signals must be software configured via BIOS programming of the APIC register space to be used either as NMI/INTR or LINT[1:0]. Because the APIC is enabled by default after Reset, operation of these pins as LINT[1:0] is the default configuration.	3
LOCK#	I/O	LOCK# indicates to the system that a transaction must occur atomically. This signal must connect the appropriate pins of all processor front side bus agents. For a locked sequence of transactions, LOCK# is asserted from the beginning of the first transaction to the end of the last transaction. When the priority agent asserts BPRI# to arbitrate for ownership of the processor front side bus, it will wait until it observes LOCK# deasserted. This enables symmetric agents to retain ownership of the processor front side bus throughout the bus locked operation and ensure the atomicity of lock.	4
MCERR#	I/O	MCERR# (Machine Check Error) is asserted to indicate an unrecoverable error without a bus protocol violation. It may be driven by all processor front side bus agents. MCERR# assertion conditions are configurable at a system level. Assertion options are defined by the following options: • Enabled or disabled. • Asserted, if configured, for internal errors along with IERR#. • Asserted, if configured, by the request initiator of a bus transaction after it observes an error. • Asserted by any bus agent when it observes an error in a bus transaction. For more details regarding machine check architecture, refer to the <i>IA-32 Software Developer's Manual, Volume 3: System Programming Guide</i>. Since multiple agents may drive this signal at the same time, MCERR# is a wire-OR signal which must connect the appropriate pins of all processor front side bus agents. In order to avoid wire-OR glitches associated with simultaneous edge transitions driven by multiple drivers, MCERR# is activated on specific clock edges and sampled on specific clock edges.	
ODTEN	I	ODTEN (On-die termination enable) should be connected to V_{CC} to enable on-die termination for end bus agents. For middle bus agents, pull this signal down via a resistor to ground to disable on-die termination. Whenever ODTE is high, on-die termination will be active, regardless of other states of the bus.	
PROCHOT#	O	PROCHOT# (processor hot) indicates that the processor Thermal Control Circuit (TCC) has been activated. Under most conditions, PROCHOT# will go active when the processor's thermal sensor detects that the processor has reached its maximum safe operating temperature. See Section 7.3 for more details. These signals do not have on-die termination and must be terminated at the end agent. See the appropriate Platform Design Guideline for additional information.	

Table 41. Signal Definitions (Page 7 of 10)

Name	Type	Description	Notes
PWRGOOD	I	PWRGOOD (Power Good) is an input. The processor requires this signal to be a clean indication that all processor clocks and power supplies are stable and within their specifications. "Clean" implies that the signal will remain low (capable of sinking leakage current), without glitches, from the time that the power supplies are turned on until they come within specification. The signal must then transition monotonically to a high state. Figure 13 illustrates the relationship of PWRGOOD to the RESET# signal. PWRGOOD can be driven inactive at any time, but clocks and power must again be stable before a subsequent rising edge of PWRGOOD. It must also meet the minimum pulse width specification in Table 16, and be followed by a 1 mS RESET# pulse. The PWRGOOD signal must be supplied to the processor; it is used to protect internal circuits against voltage sequencing issues. It should be driven high throughout boundary scan operation.	3
REQ[4:0]#	I/O	REQ[4:0]# (Request Command) must connect the appropriate pins of all processor front side bus agents. They are asserted by the current bus owner to define the currently active transaction type. These signals are source synchronous to ADSTB[1:0]#. Refer to the AP[1:0]# signal description for details on parity checking of these signals.	4
RESET#	I	Asserting the RESET# signal resets all processors to known states and invalidates their internal caches without writing back any of their contents. For a power-on Reset, RESET# must stay active for at least one millisecond after Vcc and BCLK have reached their proper specifications. On observing active RESET#, all front side bus agents will deassert their outputs within two clocks. RESET# must not be kept asserted for more than 10ms. A number of bus signals are sampled at the active-to-inactive transition of RESET# for power-on configuration. These configuration options are described in the Section 7.1. This signal does not have on-die termination and must be terminated at the end agent. See the appropriate Platform Design Guideline for additional information.	4
RS[2:0]#	I	RS[2:0]# (Response Status) are driven by the response agent (the agent responsible for completion of the current transaction), and must connect the appropriate pins of all processor front side bus agents.	4
RSP#	I	RSP# (Response Parity) is driven by the response agent (the agent responsible for completion of the current transaction) during assertion of RS[2:0]#, the signals for which RSP# provides parity protection. It must connect to the appropriate pins of all processor front side bus agents. A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. While RS[2:0]# = 000, RSP# is also high, since this indicates it is not being driven by any agent guaranteeing correct parity.	4
SKTOCC#	O	SKTOCC# (Socket occupied) will be pulled to ground by the processor to indicate that the processor is present.	
SLP#	I	SLP# (Sleep), when asserted in Stop-Grant state, causes processors to enter the Sleep state. During Sleep state, the processor stops providing internal clock signals to all units, leaving only the Phase-Locked Loop (PLL) still operating. Processors in this state will not recognize snoops or interrupts. The processor will recognize only assertion of the RESET# signal, deassertion of SLP#, and removal of the BCLK input while in Sleep state. If SLP# is deasserted, the processor exits Sleep state and returns to Stop-Grant state, restarting its internal clock signals to the bus and processor core units.	3
SM_ALERT#	O	SM_ALERT# is an asynchronous interrupt line associated with the SMBus Thermal Sensor device. It is an open-drain output and the processor includes a 10 K Ω pull-up resistor to SM_VCC for this signal. For more information on the usage of the SM_ALERT# pin, see Section 7.4.5 .	

Table 41. Signal Definitions (Page 8 of 10)

Name	Type	Description	Notes
SM_CLK	I/O	The SM_CLK (SMBus Clock) signal is an input clock to the system management logic which is required for operation of the system management features of the processor. This clock is driven by the SMBus controller and is asynchronous to other clocks in the processor. The processor includes a 10 K Ω pull-up resistor to SM_V _{CC} for this signal.	
SM_DAT	I/O	The SM_DAT (SMBus Data) signal is the data signal for the SMBus. This signal provides the single-bit mechanism for transferring data between SMBus devices. The processor includes a 10 K Ω pull-up resistor to SM_V _{CC} for this signal.	
SM_EP_A[2:0]	I	The SM_EP_A (EEPROM Select Address) pins are decoded on the SMBus in conjunction with the upper address bits in order to maintain unique addresses on the SMBus in a system with multiple processors. To set an SM_EP_A line high, a pull-up resistor should be used that is no larger than 1 K Ω . The processor includes a 10 K Ω pull-down resistor to V _{SS} for each of these signals. For more information on the usage of these pins, see Section 7.4.8 .	
SM_TS_A[1:0]	I	The SM_TS_A (Thermal Sensor Select Address) pins are decoded on the SMBus in conjunction with the upper address bits in order to maintain unique addresses on the SMBus in a system with multiple processors. The device's addressing, as implemented, includes a Hi-Z state for both address pins. The use of the Hi-Z state is achieved by leaving the input floating (unconnected). For more information on the usage of these pins, see Section 7.4.8 .	
SM_V _{CC}	I	Provides power to the SMBus components on the processor, as well as to the processor VID logic. The baseboard MUST provide SM_V _{CC} to the processor. See Figure 19 "Example 3.3 VDC/SM_VCC Sequencing" on page 44 for further details.	
SM_WP	I	WP (Write Protect) can be used to write protect the Scratch EEPROM. The Scratch EEPROM is write-protected when this input is pulled high to SM_V _{CC} . The processor includes a 10 K Ω pull-down resistor to V _{SS} for this signal.	
SMI#	I	SMI# (System Management Interrupt) is asserted asynchronously by system logic. On accepting a System Management Interrupt, processors save the current state and enter System Management Mode (SMM). An SMI Acknowledge transaction is issued, and the processor begins program execution from the SMM handler. If SMI# is asserted during the deassertion of RESET# the processor will tri-state its outputs.	3
STPCLK#	I	STPCLK# (Stop Clock), when asserted, causes processors to enter a low power Stop-Grant state. The processor issues a Stop-Grant Acknowledge transaction, and stops providing internal clock signals to all processor core units except the front side bus and APIC units. The processor continues to snoop bus transactions and service interrupts while in Stop-Grant state. When STPCLK# is deasserted, the processor restarts its internal clock to all units and resumes execution. The assertion of STPCLK# has no effect on the bus clock; STPCLK# is an asynchronous input.	3
TCK	I	TCK (Test Clock) provides the clock input for the processor Test Bus (also known as the Test Access Port).	
TDI	I	TDI (Test Data In) transfers serial test data into the processor. TDI provides the serial input needed for JTAG specification support.	
TDO	O	TDO (Test Data Out) transfers serial test data out of the processor. TDO provides the serial output needed for JTAG specification support.	

Table 41. Signal Definitions (Page 9 of 10)

Name	Type	Description	Notes
TESTHI[6:0]	I	All TESTHI[6:0] pins should be individually connected to VCC via a pull-up resistor which matches the trace impedance within a range of ± 10 ohms. TESTHI[3:0] and TESTHI[6:5] may all be tied together and pulled up to VCC with a single resistor if desired. However, utilization of boundary scan test will not be functional if these pins are connected together. TESTHI4 must always be pulled up independently from the other TESTHI pins. For optimum noise margin, all pull-up resistor values used for TESTHI[6:0] pins should have a resistance value within ± 20 percent of the impedance of the baseboard transmission line traces. For example, if the trace impedance is 50Ω , then a value between 40Ω and 60Ω should be used. The TESTHI[6:0] termination recommendations provided in the Intel® Xeon™ processor datasheet are still suitable for the Intel® Xeon™ processor with 512 KB L2 cache. However, Intel recommends new designs or designs undergoing design updates follow the trace impedance matching termination guidelines given in this section.	
THERMTRIP#	O	Activation of THERMTRIP# (Thermal Trip) indicates the processor junction temperature has reached a level beyond which permanent silicon damage may occur. Measurement of the temperature is accomplished through an internal thermal sensor which is configured to trip at approximately 135°C . To properly protect the processor, power must be removed upon THERMTRIP# becoming active. See Figure 16 and Table 20 for the appropriate power down sequence and timing requirement. In parallel, the processor will attempt to reduce its temperature by shutting off internal clocks and stopping all program execution. Once activated, THERMTRIP# remains latched and the processor will be stopped until RESET# is asserted. A RESET# pulse will reset the processor and execution will begin at the boot vector. If the temperature has not dropped below the trip level, the processor will assert THERMTRIP# and return to the shutdown state. The processor releases THERMTRIP# when RESET# is activated even if the processor is still too hot. This signal do not have on-die termination and must be terminated at the end agent. See the appropriate platform design guidelines for additional information.	2
TMS	I	TMS (Test Mode Select) is a JTAG specification support signal used by debug tools. This signal does not have on-die termination and must be terminated at the end agent. See the appropriate platform design guidelines for additional information.	
TRDY#	I	TRDY# (Target Ready) is asserted by the target to indicate that it is ready to receive a write or implicit writeback data transfer. TRDY# must connect the appropriate pins of all front side bus agents.	
TRST#	I	TRST# (Test Reset) resets the Test Access Port (TAP) logic. TRST# must be driven low during power on Reset. See the appropriate Platform Design Guideline for additional information.	
V _{CCA}	I	VCCA provides isolated power for the analog portion of the internal PLL's. Use a discrete RLC filter to provide clean power. Use the filter defined in Section 2.5 to provide clean power to the PLL. The tolerance and total ESR for the filter is important. Refer to the appropriate platform design guidelines for complete implementation details.	
V _{CCIOPLL}	I	V _{CCIOPLL} provides isolated power for digital portion of the internal PLL's. Follow the guidelines for V _{CCA} (Section 2.5), and refer to the appropriate platform design guidelines for complete implementation details.	
V _{CCSENSE} V _{SSSENSE}	O	The Vccsense and Vssense pins are the points for which processor minimum and maximum voltage requirements are specified. Uniprocessor designs may utilize these pins for voltage sensing for the processor's voltage regulator. However, multi-processor designs must not connect these pins to sense logic, but rather utilize them for power delivery validation.	

Table 41. Signal Definitions (Page 10 of 10)

Name	Type	Description	Notes
VID[4:0]	O	VID[4:0] (Voltage ID) pins can be used to support automatic selection of power supply voltages (V_{CC}). Unlike previous processor generations, these pins are driven by processor logic. Hence the voltage supply for these pins (SM_V_{CC}) must be valid before the VRM supplying V_{CC} to the processor is enabled. Conversely, the VRM output must be disabled prior to the voltage supply for these pins becomes invalid. The VID pins are needed to support processor voltage specification variations. See Table 3 for definitions of these pins. The power supply must supply the voltage that is requested by these pins, or disable itself.	
V_{SSA}	I	V_{SSA} provides an isolated, internal ground for internal PLL's. Do not connect directly to ground. This pin is to be connected to V_{CCA} and $V_{CCIOPLL}$ through a discrete filter circuit.	

NOTES:

1. Intel Xeon processors only support BR0# and BR1#. However, the Intel Xeon processors must terminate BR2# and BR3# to the processor V_{CC} .
2. For this pin on Intel® Xeon™ processors, the maximum number of symmetric agents is one. Maximum number of Central Agents is zero.
3. For this pin on Intel® Xeon™ processors, the maximum number of symmetric agents is two. Maximum number of Central Agents is zero.
4. For this pin on Intel® Xeon™ processors, the maximum number of symmetric agents is two. Maximum number of Central Agents is one.

6.0 Thermal Specifications

This chapter provides the thermal specifications necessary for designing a thermal solution for the Intel® Xeon™ processor with 512 KB L2 cache. Thermal solutions should include heatsinks that attach to the integrated heat spreader (IHS). The IHS provides a common interface intended to be compatible with many heatsink designs. Thermal specifications are based on the temperature of the IHS top, referred to as the case temperature, or T_{CASE} . Thermal solutions should be designed to maintain the processor within T_{CASE} specifications. For information on performing T_{CASE} measurements, refer to the *Intel® Xeon™ Processor Thermal Design Guidelines*. See [Figure 37](#) for an exploded view of the processor package and thermal solution assembly.

Note: The processor is either shipped alone or with a heatsink (boxed processor only). All other components shown in [Figure 37](#) must be purchased separately.

Figure 37. Processor with Thermal and Mechanical Components - Exploded View

Note: This is a graphical representation. For specifications, see each component's respective documentation listed in [Section 1.3](#).

6.1 Thermal Specifications

Table 42 specifies the thermal design power dissipation envelope for the Intel® Xeon™ processor with 512 KB L2 cache. The processor power listed in Table 42 is described in thermal design power. Analysis indicates that real applications are unlikely to cause the processor to consume the maximum possible power consumption. Intel recommends that system thermal designs utilize the Thermal Design Power indicated in Table 42. Thermal Design Power recommendations are chosen through characterization of server and workstation applications on the processor.

The Thermal Monitor feature is intended to protect the processor from overheating on any high power code that exceeds the recommendations in this table. For more details on the Thermal Monitor feature, refer to Section 7.3. In all cases, the Thermal Monitor feature must be enabled for the processor to be operating within specification. Table 42 also lists the minimum and maximum processor T_{CASE} temperature specifications. A thermal solution should be designed to ensure the temperature of the processor never exceeds these specifications.

Table 42. Processor Thermal Design Power

Core Frequency	Thermal Design Power ¹ (W)	Minimum T_{CASE} (°C)	Maximum T_{CASE} (°C)	Notes
1.80 GHz	55	5	69	2, 3
2 GHz	58	5	70	2, 3
2.20 GHz	61	5	75	2, 3
2.40 GHz	65	5	74	2, 3
2.60 GHz	71	5	74	2, 3
2.80 GHz	74	5	75	2, 3
3 GHz	85	5	73	2, 3

NOTE:

1. Intel recommends that thermal solutions be designed utilizing the Thermal Design Power values. Refer to the *Intel® Xeon™ Processor Thermal Design Guidelines*.
2. TDP values are specified at the point on V_{cc_max} loadline corresponding to I_{cc_TDP} .
3. Systems must be designed to ensure that the processor is not subjected to any static V_{cc} and I_{cc} combination wherein V_{cc} exceeds V_{cc_max} at specified I_{cc} . Please refer to the loadline specifications in Chapter 2.0.

Figure 38. Processor Thermal Design Power vs Electrical Projections for VID = 1.500V

Figure 39. Processor Thermal Design Power vs Electrical Projections for VID = 1.525V

6.2 Measurements for Thermal Specifications

6.2.1 Processor Case Temperature Measurement

The minimum and maximum case temperatures (T_{CASE}) for processors are specified in Table 42 of the previous section. These temperature specifications are meant to ensure correct and reliable operation of the processor. Figure 40 illustrates the thermal measurement point for T_{CASE} . This point is at the geometric center of the integrated heat spreader (IHS).

Figure 40. Thermal Measurement Point for Processor T_{CASE}

Note: Figure is not to scale, and is for reference only

7.0 Features

7.1 Power-On Configuration Options

The Intel® Xeon™ processor with 512 KB L2 cache has several configuration options that are determined by the state of specific processor pins at the active-to-inactive transition of the processor RESET# signal. These configuration options cannot be changed except by another reset. Both power on and software induced resets reconfigure the processor(s).

Table 43. Power-On Configuration Option Pins

Configuration Option	Pin ¹	Notes
Output tri state	SMI#	
Execute BIST (Built-In Self Test)	INIT#	
In Order Queue de-pipelining (set IOQ depth to 1)	A7#	
Disable MCERR# observation	A9#	
Disable BINIT# observation	A10#	
APIC cluster ID (0-3)	A[12:11]#	2
Disable bus parking	A15#	
Disable Hyper-Threading Technology	A31#	
Symmetric agent arbitration ID	BR[3:0]#	3

NOTES:

1. Asserting this signal during active-to-inactive edge of RESET# will selects the corresponding option.
2. The Intel® Xeon™ processor with 512 KB L2 cache does not support this feature, therefore platforms utilizing this processor should not use these configuration pins.
3. Intel Xeon processor with 512 KB L2 cache utilize only BR0# and BR1# signals. 2-way platforms must not utilize BR2# and BR3# signals.

7.2 Clock Control and Low Power States

The processor allows the use of AutoHALT, Stop-Grant and Sleep states to reduce power consumption by stopping the clock to internal sections of the processor, depending on each particular state. See [Figure 41](#) for a visual representation of the processor low power states.

Due to the inability of processors to recognize bus transactions during the Sleep state, multiprocessor systems are not allowed to simultaneously have one processor in Sleep state and the other processor in the Normal or Stop-Grant state.

7.2.1 Normal State—State 1

This is the normal operating state for the processor.

7.2.2 AutoHALT Powerdown State—State 2

AutoHALT is a low power state entered when the processor executes the HALT instruction. The processor will transition to the Normal state upon the occurrence of SMI#, BINIT#, INIT#, LINT[1:0] (NMI, INTR), or an interrupt delivered over the front side bus. RESET# will cause the processor to immediately initialize itself.

The return from a System Management Interrupt (SMI) handler can be to either Normal Mode or the AutoHALT Power Down state. See the *Intel Architecture Software Developer's Manual, Volume III: System Programmer's Guide* for more information.

The system can generate a STPCLK# while the processor is in the AutoHALT Power Down state. When the system deasserts the STPCLK# interrupt, the processor will return execution to the HALT state.

Figure 41. Stop Clock State Machine

7.2.3 Stop-Grant State—State 3

When the STPCLK# pin is asserted, the Stop-Grant state of the processor is entered 20 bus clocks after the response phase of the processor-issued Stop Grant Acknowledge special bus cycle. Once the STPCLK# pin has been asserted, it may only be deasserted once the processor is in the Stop Grant state. Both logical processors of the Intel® Xeon™ processor with 512 KB L2 cache must be in the Stop Grant state before the deassertion of STPCLK#.

Since the AGTL+ signal pins receive power from the front side bus, these pins should not be driven (allowing the level to return to V_{CC}) for minimum power drawn by the termination resistors in this state. In addition, all other input pins on the front side bus should be driven to the inactive state.

BINIT# will be recognized while the processor is in Stop-Grant state. If STPCLK# is still asserted at the completion of the BINIT# bus initialization, the processor will remain in Stop-Grant mode. If the STPCLK# is not asserted at the completion of the BINIT# bus initialization, the processor will return to Normal state.

RESET# will cause the processor to immediately initialize itself, but the processor will stay in Stop-Grant state. A transition back to the Normal state will occur with the deassertion of the STPCLK# signal. When re-entering the Stop-Grant state from the sleep state, STPCLK# should only be deasserted one or more bus clocks after the deassertion of SLP#.

A transition to the HALT/Grant Snoop state will occur when the processor detects a snoop on the front side bus (see [Section 7.2.4](#)). A transition to the Sleep state (see [Section 7.2.5](#)) will occur with the assertion of the SLP# signal.

While in the Stop-Grant state, SMI#, INIT#, BINIT# and LINT[1:0] will be latched by the processor, and only serviced when the processor returns to the Normal state. Only one occurrence of each event will be recognized upon return to the Normal state.

7.2.4 HALT/Grant Snoop State—State 4

The processor will respond to snoop transactions on the front side bus while in Stop-Grant state or in AutoHALT Power Down state. During a snoop transaction, the processor enters the HALT/Grant Snoop state. The processor will stay in this state until the snoop on the front side bus has been serviced (whether by the processor or another agent on the front side bus). After the snoop is serviced, the processor will return to the Stop-Grant state or AutoHALT Power Down state, as appropriate.

7.2.5 Sleep State—State 5

The Sleep state is a very low power state in which each processor maintains its context, maintains the phase-locked loop (PLL), and has stopped most of internal clocks. The Sleep state can only be entered from Stop-Grant state. Once in the Stop-Grant state, the SLP# pin can be asserted, causing the processor to enter the Sleep state. The SLP# pin is not recognized in the Normal or AutoHALT states.

Snoop events that occur while in Sleep state or during a transition into or out of Sleep state will cause unpredictable behavior.

In the Sleep state, the processor is incapable of responding to snoop transactions or latching interrupt signals. No transitions or assertions of signals (with the exception of SLP# or RESET#) are allowed on the front side bus while the processor is in Sleep state. Any transition on an input signal before the processor has returned to Stop-Grant state will result in unpredictable behavior.

If RESET# is driven active while the processor is in the Sleep state, and held active as specified in the RESET# pin specification, then the processor will reset itself, ignoring the transition through Stop-Grant state. If RESET# is driven active while the processor is in the Sleep state, the SLP# and STPCLK# signals should be deasserted immediately after RESET# is asserted to ensure the processor correctly executes the reset sequence.

Once in the Sleep state, the SLP# pin can be deasserted if another asynchronous front side bus event occurs. The SLP# pin should only be asserted when the processor **(and all logical processors within the physical processor)** is in the Stop-Grant state. SLP# assertions while the processors are not in the Stop-Grant state is out of specification and may result in illegal operation.

7.2.6 Bus Response During Low Power States

While in AutoHALT Power Down and Stop-Grant states, the processor will process a front side bus snoop.

When the processor is in Sleep state, the processor will not process interrupts or snoop transactions.

7.3 Thermal Monitor

Thermal Monitor is a feature of the processor that allows system designers to lower the cost of thermal solutions, without compromising system integrity or reliability. By using a factory-tuned, precision on-die temperature sensor, and a fast acting thermal control circuit (TCC), the processor, without the aid of any additional software or hardware, can control the processors' die temperature within factory specifications under typical real-world operating conditions. Thermal Monitor thus allows the processor and system thermal solutions to be designed much closer to the power envelopes of real applications, instead of being designed to the much higher maximum processor power envelopes.

Thermal Monitor controls the processor temperature by modulating (starting and stopping) the internal processor core clocks. The processor clocks are modulated when the thermal control circuit (TCC) is activated. Thermal Monitor uses two modes to activate the TCC: Automatic mode and On-Demand mode. **Automatic mode must be enabled via BIOS, which is required for the processor to operate within specifications.** Once automatic mode is enabled, the TCC will activate only when the internal die temperature is very near the temperature limits of the processor. When the TCC is enabled, and a high temperature situation exists (i.e. TCC is active), the clocks will be modulated by maintaining a duty cycle within a range of 30% - 50%. Clocks will not be off or on more than 3.0 ms when the TCC is active. Cycle times are processor speed dependent and will decrease as processor core frequencies increase. A small amount of hysteresis has been included to prevent rapid active/inactive transitions of the TCC when the processor temperature is near the trip point. Once the temperature has returned to a non-critical level, and the hysteresis timer has expired, modulation ceases and the TCC goes inactive. Processor performance will be decreased by ~50% when the TCC is active (assuming a duty cycle that varies from 30%-50%), however, with a properly designed and characterized thermal solution the TCC most likely will only be activated briefly during the most power intensive applications while at maximum chassis ambient temperature.

For automatic mode, the duty cycle is factory configured and cannot be modified. Also, automatic mode does not require any additional hardware, software drivers or interrupt handling routines.

The TCC may also be activated via On-Demand mode. If bit 4 of the ACPI Thermal Monitor Control Register is written to a “1” the TCC will be activated immediately, independent of the processor temperature. When using On-Demand mode to activate the TCC, the duty cycle of the clock modulation is programmable via bits 3:1 of the same ACPI Thermal Monitor Control Register. In automatic mode, the duty cycle is fixed anywhere within a range of 30% to 50%; however in On-Demand mode, the duty cycle can be programmed from 12.5% on/ 87.5% off, to 87.5% on/12.5% off in 12.5% increments. On-Demand mode may be used at the same time Automatic mode is enabled, however, if TCC is enabled via On-Demand mode at the same time automatic mode is enabled AND a high temperature condition exists, the fixed duty cycle of the automatic mode will override the duty cycle selected by the On-Demand mode.

An external signal, PROCHOT# (processor hot) is asserted at any time the TCC is active (either in Automatic or On-Demand mode). Bus snooping and interrupt latching are also active while the TCC is active. The temperature at which the thermal control circuit activates is not user configurable and is not software visible. In an MP system, Thermal Monitor must be configured identically for each processor within the system.

Besides the thermal sensor and thermal control circuit, the Thermal Monitor feature also includes one ACPI register, one performance counter register, three model specific registers (MSR), and one I/O pin (PROCHOT#). All are available to monitor and control the state of the Thermal Monitor feature. Thermal Monitor can be configured to generate an interrupt upon the assertion or deassertion of PROCHOT# (i.e. upon the activation/deactivation of TCC). Refer to Volume 3 of the *IA32 Intel Architecture Software Developer's* for specific register and programming details.

If automatic mode is disabled the processor will be operating out of specification and cannot be guaranteed to provide reliable results. Regardless of enabling of the automatic or On-Demand modes, in the event of a catastrophic cooling failure, the processor will automatically shut down when the silicon has reached a temperature of approximately 135 °C. At this point the front side bus signal THERMTRIP# will go active and stay active until the processor has cooled down and RESET# has been initiated. THERMTRIP# activation is independent of processor activity and does not generate any bus cycles. If THERMTRIP# is asserted, processor core voltage (V_{CC}) must be removed within the timeframe defined in [Figure 16](#).

7.3.1 Thermal Diode

The processor incorporates an on-die thermal diode. A thermal sensor located on the processor may be used to monitor the die temperature of the processor for thermal management/long term die temperature change purposes. This thermal diode is separate from the Thermal Monitor's thermal sensor and cannot be used to predict the behavior of the Thermal Monitor. See [Section 7.4.4](#) for details.

7.4 System Management Bus (SMBus) Interface

The processor includes an SMBus interface which allows access to a memory component with two sections (referred to as the Processor Information ROM and the Scratch EEPROM) and a thermal sensor on the substrate. The SMBus thermal sensor may be used to read the thermal diode mentioned in [Section 7.3.1](#). These devices and their features are described below. See [Chapter 4.0](#) for the physical location of these devices.

Note: The SMBus thermal sensor and its associated thermal diode are not related to, and are completely independent of, the precision on-die temperature sensor and thermal control circuit (TCC) of the Thermal Monitor feature discussed in [Section 7.3](#).

The processor SMBus implementation uses the clock and data signals of the V1.1 *System Management Bus Specification*. It does not implement the SMBSUS# signal. Layout and routing guidelines are available in the appropriate platform design guidelines document.

For platforms which do not implement any of the SMBus features found on the processor, all of the SMBus connections to the socket pins, **except SM_VCC**, may be left unconnected (SM_ALERT#, SM_CLK, SM_DAT, SM_EP_A[2:0], SM_TS_A[1:0], SM_WP). **SM_VCC provides power to the VID generation logic in addition to supplying the SMBus and must be supplied with 3.3 volt power to assure correct setting of the processor core voltage (V_{CC}).**

Figure 42. Logical Schematic of SMBus Circuitry

NOTE: Actual implementation may vary. For use in general understanding of the architecture. All SMBus pull-up and pull-down resistors are 10K ohms and located on the processor.

7.4.1 Processor Information ROM (PIROM)

The lower half (128 bytes) of the SMBus memory component is an electrically programmed read-only memory with information about the processor. This information is permanently write-protected. [Table 44](#) shows the data fields and formats provided in the Processor Information ROM (PIROM).

Table 44. Processor Information ROM Format (Page 1 of 2)

Offset/Section	# of Bits	Function	Notes

7.4.2 Scratch EEPROM

Also available in the memory component on the processor SMBus is an EEPROM which may be used for other data at the system or processor vendor's discretion. The data in this EEPROM, once programmed, can be write-protected by asserting the active-high SM_WP signal. This signal has a weak pull-down (10 kW) to allow the EEPROM to be programmed in systems with no implementation of this signal. The Scratch EEPROM resides in the upper half of the memory component (addresses 80 - FFh). The lower half comprises the Processor Information ROM (address 00 - 7Fh), which is permanently write protected by Intel.

7.4.3 PIROM and Scratch EEPROM Supported SMBus Transactions

The Processor Information ROM (PIR) responds to two SMBus packet types: Read Byte and Write Byte. However, since the PIR is write-protected, it will acknowledge a Write Byte command but ignore the data. The Scratch EEPROM responds to Read Byte and Write Byte commands. Table 45 diagrams the Read Byte command. Table 46 diagrams the Write Byte command. Following a write cycle to the scratch ROM, software must allow a minimum of 10ms before accessing either ROM of the processor.

In the tables, 'S' represents the SMBus start bit, 'P' represents a stop bit, 'R' represents a read bit, 'W' represents a write bit, 'A' represents an acknowledge (ACK), and '///' represents a negative acknowledge (NACK). The shaded bits are transmitted by the Processor Information ROM or Scratch EEPROM, and the bits that aren't shaded are transmitted by the SMBus host controller. In the tables the data addresses indicate 8 bits. The SMBus host controller should transmit 8 bits with the most significant bit indicating which section of the EEPROM is to be addressed: the Processor Information ROM (MSB = 0) or the Scratch EEPROM (MSB = 1).

Table 45. Read Byte SMBus Packet

S	Slave Address	Write	A	Command Code	A	S	Slave Address	Read	A	Data	///	P
1	7-bits	1	1	8-bits	1	1	7-bits	1	1	8-bits	1	1

Table 46. Write Byte SMBus Packet

S	Slave Address	Write	A	Command Code	A	Data	A	P
1	7-bits	1	1	8-bits	1	8-bits	1	1

7.4.4 SMBus Thermal Sensor

The processor's SMBus thermal sensor provides a means of acquiring thermal data from the processor. The thermal sensor is composed of control logic, SMBus interface logic, a precision analog-to-digital converter, and a precision current source. The sensor drives a small current through the p-n junction of a thermal diode located on the processor core. The forward bias voltage generated across the thermal diode is sensed and the precision A/D converter derives a single byte of thermal reference data, or a "thermal byte reading." The nominal precision of the least significant bit of a thermal byte is 1 °C.

The processor incorporates the SMBus thermal sensor and thermal reference byte onto the processor package as was previously done on Intel® Xeon™ processor family. Upper and lower thermal reference thresholds can be individually programmed for the SMBus thermal sensor. Comparator circuits sample the register where the single byte of thermal data (thermal byte

reading) is stored. These circuits compare the single byte result against programmable threshold bytes. If enabled, the alert signal on the processor SMBus (SM_ALERT#) will be asserted when the sensor detects that either threshold is reached or crossed. Analysis of SMBus thermal sensor data may be useful in detecting changes in the system environment that may require attention.

During manufacturing, the thermal reference byte (TRB) is programmed into the Processor Information ROM. The thermal reference byte represents the approximate thermal byte reading that is obtained when the processor is operating at its maximum specified T_{CASE} . The TRB is derived for each individual processor during Intel's manufacturing process.

The processor SMBus thermal sensor and thermal reference byte may be used to monitor long term temperature trends, but can not be used to manage the short term temperature of the processor or predict the activation of the thermal control circuit. As mentioned earlier, the processors high thermal ramp rates make this infeasible. Refer to the *Intel® Xeon™ Processor Family Thermal Design Guidelines* for more details.

The SMBus thermal sensor feature in the processor cannot be used to measure T_{CASE} . The T_{CASE} specification in [Chapter 6.0](#) must be met regardless of the reading of the processor's thermal sensor in order to ensure adequate cooling for the processor. The SMBus thermal sensor feature is only available while V_{CC} and SM_V_{CC} are at valid levels and the processor is not in a low-power state.

7.4.5 Thermal Sensor Supported SMBus Transactions

The thermal sensor responds to five of the SMBus packet types: Write Byte, Read Byte, Send Byte, Receive Byte, and Alert Response Address (ARA). The Send Byte packet is used for sending one-shot commands only. The Receive Byte packet accesses the register commanded by the last Read Byte packet and can be used to continuously read from a register. If a Receive Byte packet was preceded by a Write Byte or send Byte packet more recently than a Read Byte packet, then the behavior is undefined. [Table 47](#) through [Table 50](#) diagram the five packet types. In these figures, 'S' represents the SMBus start bit, 'P' represents a stop bit, 'Ack' represents an acknowledge, and '///' represents a negative acknowledge (NACK). The shaded bits are transmitted by the thermal sensor, and the bits that aren't shaded are transmitted by the SMBus host controller. [Table 51](#) shows the encoding of the command byte.

Table 47. Write Byte SMBus Packet

S	Slave Address	Write	Ack	Command Code	Ack	Data	Ack	P
1	7-bits	1	1	8-bits	1	8-bits	1	1

Table 48. Read Byte SMBus Packet

S	Slave Address	Write	Ack	Command Code	Ack	S	Slave Address	Read	Ack	Data	///	P
1	7-bits	1	1	8-bits	1	1	7-bits	1	1	8-bits	1	1

Table 49. Send Byte SMBus PacketReceive Byte SMBus Packet

S	Slave Address	Read	Ack	Command Code	Ack	P
1	7-bits	1	1	8-bits	1	1
S	Slave Address	Read	Ack	Data	///	P
1	7-bits	1	1	8-bits	1	1

Table 50. ARA SMBus Packet

S	ARA	Read	Ack	Address	///	P
1	0001 100	1	1	Device Address ¹	1	1

NOTE:

1. This is an 8-bit field. The device which sent the alert will respond to the ARA Packet with its address in the seven most significant bits. The least significant bit is undefined and may return as a '1' or '0'. See [Section 7.4.8](#) for details on the Thermal Sensor Device addressing.

Table 51. SMBus Thermal Sensor Command Byte Bit Assignments

Register	Command	Reset State	Function
RESERVED	00h	RESERVED	Reserved for future use
TRR	01h	0000 0000	Read processor core thermal diode
RS	02h	N/A	Read status byte (flags, busy signal)
RC	03h	00XX XXXX	Read configuration byte
RCR	04h	0000 0010	Read conversion rate byte
RESERVED	05h	RESERVED	Reserved for future use
RESERVED	06h	RESERVED	Reserved for future use
RRHL	07h	0111 1111	Read processor core thermal diode T _{HIGH} limit
RRLL	08h	1100 1001	Read processor core thermal diode T _{LOW} limit
WC	09h	N/A	Write configuration byte
WCR	0Ah	N/A	Write conversion rate byte
RESERVED	0Bh	RESERVED	Reserved for future use
RESERVED	0Ch	RESERVED	Reserved for future use
WRHL	0Dh	N/A	Write processor core thermal diode T _{HIGH} limit
WRLL	0Eh	N/A	Write processor core thermal diode T _{LOW} limit
OSHT	0Fh	N/A	One shot command (use send byte packet)
RESERVED	10h – FFh	N/A	Reserved for future use

All of the commands in [Table 51](#) are for reading or writing registers in the SMBus thermal sensor, except the one-shot command (OSHT) register. The one-shot command forces the immediate start of a new conversion cycle. If a conversion is in progress when the one-shot command is received, then the command is ignored. If the thermal sensor is in stand-by mode when the one-shot command is received, a conversion is performed and the sensor returns to stand-by mode. The one-shot command is not supported when the thermal sensor is in auto-convert mode.

Note: Writing to a read-command register or reading from a write-command register will produce invalid results.

The default command after reset is to a reserved value (00h). After reset, “Receive Byte” SMBus packets will return invalid data until another command is sent to the thermal sensor.

7.4.6 SMBus Thermal Sensor Registers

7.4.6.1 Thermal Reference Registers

Once the SMBus thermal sensor reads the processor thermal diode, it performs an analog to digital conversion and stores the result in the Thermal Reference Register (TRR). The supported range is +127 to 0 decimal and is expressed as an eight-bit number representing temperature in degrees Celsius. This eight-bit value consists of seven data bits and a sign bit (MSB) as shown in [Table 52](#). The values shown are also used to program the Thermal Limit Registers.

The values of these registers should be treated as saturating values. Values above 127 are represented as 127 decimal, while values of zero and below may be represented as 0 to -127 decimal. If the thermal sensor returns a value with the sign bit set (1) and the data is 000_0000 through 111_1110, the temperature should be interpreted as 0 °C.

Table 52. Thermal Reference Register Values

Temperature (°C)	Register Value (binary)
+127	0 111 1111
+126	0 111 1110
+100	0 110 0100
+50	0 011 0010
+25	0 001 1001
+1	0 000 0001
0	0 000 0000

7.4.6.2 Thermal Limit Registers

The SMBus thermal sensor has four Thermal Limit Registers: RRHL is used to read the high limit; RRLl is read for the low limit; WRHL is used to write the high limit; and the WRLL to write the low limit. These registers allow the user to define high and low limits for the processor core thermal diode reading. The encoding for these registers is the same as for the Thermal Reference Register shown in [Table 52](#). If the processor thermal diode reading equals or exceeds one of these limits, then the alarm bit (RHIGH or RLOW) in the Thermal Sensor Status Register is triggered.

7.4.6.3 Status Register

The Status Register shown in [Table 53](#) indicates which (if any) thermal value thresholds for the processor core thermal diode have been exceeded. It also indicates if a conversion is in progress or if an open circuit has been detected in the processor core thermal diode connection. Once set, alarm bits stay set until they are cleared by a Status Register read. A successful read to the Status Register will clear any alarm bits that may have been set, unless the alarm condition persists. If the SM_ALERT# signal is enabled via the Thermal Sensor Configuration Register and a thermal diode threshold is exceeded, an alert will be sent to the platform via the SM_ALERT# signal.

This register is read by accessing the RS Command Register.

Table 53. SMBus Thermal Sensor Status Register

Bit	Name	Reset State	Function
7 (MSB)	BUSY	N/A	If set, indicates that the device's analog to digital converter is busy.
6	RESERVED	RESERVED	Reserved for future use
5	RESERVED	RESERVED	Reserved for future use
4	RHIGH	0	If set, indicates the processor core thermal diode high temperature alarm has activated.
3	RLOW	0	If set, indicates the processor core thermal diode low temperature alarm has activated.
2	OPEN	0	If set, indicates an open fault in the connection to the processor core diode.
1	RESERVED	RESERVED	Reserved for future use.
0 (LSB)	RESERVED	RESERVED	Reserved for future use.

7.4.6.4 Configuration Register

The Configuration Register controls the operating mode (stand-by vs. auto-convert) of the SMBus thermal sensor. [Table 54](#) shows the format of the Configuration Register. If the RUN/STOP bit is set (high) then the thermal sensor immediately stops converting and enters stand-by mode. The thermal sensor will still perform analog to digital conversions in stand-by mode when it receives a one-shot command. If the RUN/STOP bit is clear (low) then the thermal sensor enters auto-conversion mode.

This register is accessed by using the thermal sensor Command Register: The RC command register is used for read commands and the WC command register is used for write commands. See [Table 51](#).

Table 54. SMBus Thermal Sensor Configuration Register

Bit	Name	Reset State	Function
7 (MSB)	MASK	0	Mask SM_ALERT# bit. Clear bit to allow interrupts via SM_ALERT# and allow the thermal sensor to respond to the ARA command when an alarm is active. Set the bit to disable interrupt mode. The bit is not used to clear the state of the SM_ALERT# output. An ARA command may not be recognized if the mask is enabled.
6	RUN/STOP	0	Stand-by mode control bit. If set, the device immediately stops converting, and enters stand-by mode. If cleared, the device converts in either one-shot mode or automatically updates on a timed basis.
5:0	RESERVED	RESERVED	Reserved for future use.

7.4.6.5 Conversion Rate Registers

The contents of the Conversion Rate Registers determine the nominal rate at which analog to digital conversions happen when the SMBus thermal sensor is in auto-convert mode. There are two Conversion Rate Registers, RCR for reading the conversion rate value and WCR for writing the value. Table 55 shows the mapping between Conversion Rate Register values and the conversion rate. As indicated in Table 51, the Conversion Rate Register is set to its default state of 02h (0.25 Hz nominally) when the thermal sensor is powered up. There is a $\pm 30\%$ error tolerance between the conversion rate indicated in the conversion rate register and the actual conversion rate.

Table 55. SMBus Thermal Sensor Conversion Rate Registers

Register Value	Conversion Rate (Hz)
00h	0.0625
01h	0.125
02h	0.25
03h	0.5
04h	1.0
05h	2.0
06h	4.0
07h	8.0
08h to FFh	Reserved for future use

7.4.7 SMBus Thermal Sensor Alert Interrupt

The SMBus thermal sensor located on the processor includes the ability to interrupt the SMBus when a fault condition exists. The fault conditions consist of: 1) a processor thermal diode value measurement that exceeds a user-defined high or low threshold programmed into the Command Register or 2) disconnection of the processor thermal diode from the thermal sensor. The interrupt can be enabled and disabled via the thermal sensor Configuration Register and is delivered to the baseboard via the SM_ALERT# open drain output. Once latched, the SM_ALERT# should only be cleared by reading the Alert Response byte from the Alert Response Address of the thermal sensor. The Alert Response Address is a special slave address shown in Table 50. The SM_ALERT# will

be cleared once the SMBus master device first reads the status register then reads the slave ARA unless the fault condition persists. Reading the Status Register alone or setting the mask bit within the Configuration Register does not clear the interrupt.

7.4.8 SMBus Device Addressing

Of the addresses broadcast across the SMBus, the memory component claims those of the form “1010XXXZb”. The “XXX” bits are defined by pullups and pulldowns on the system baseboard. These address pins are pulled down weakly (10 K Ω) on the processor substrate to ensure that the memory components are in a known state in systems which do not support the SMBus, or only support a partial implementation. The “Z” bit is the read/write bit for the serial bus transaction.

The thermal sensor internally decodes one of three upper address patterns from the bus of the form “0011XXXZb”, “1001XXXZb”, or “0101XXXZb”. The device’s addressing, as implemented, uses the SM_TS_A[1:0] pins in either the HI, LO, or Hi-Z state. Therefore, the thermal sensor supports nine unique addresses. To set either pin for the Hi-Z state, the pin must be left floating. As before, the “Z” bit is the read/write bit for the serial transaction.

Note that addresses of the form “0000XXXXb” are Reserved and should not be generated by an SMBus master. The thermal sensor samples and latches the SM_TS_A[1:0] signals at power-up and at the starting point of every conversion. System designers should ensure that these signals are at valid input levels before the thermal sensor powers up. This should be done by pulling the pins to SM_V_{CC} or V_{SS} via a 1 K Ω or smaller resistor, or leaving the pins floating to achieve the Hi-Z state. If the designer desires to drive the SM_TS_A[1:0] pins with logic, the designer must ensure that the pins are at input levels of 3.3V or 0V before SM_V_{CC} begins to ramp. The system designer must also ensure that their particular implementation does not add excessive capacitance to the address inputs. Excess capacitance at the address inputs may cause address recognition problems. Refer to the appropriate platform design guidelines document and the *System Management Bus Specification*.

Figure 42 on page 104 shows a logical diagram of the pin connections. Table 56 and Table 57 describe the address pin connections and how they affect the addressing of the devices.

Table 56. Thermal Sensor SMBus Addressing

Address (Hex)	Upper Address ¹	Device Select		8-bit Address Word on Serial Bus
		SM_TS_A1	SM_TS_A0	b[7:0]
3Xh	0011	0 Z ² 1	0 0 0	0011000Xb 0011001Xb 0011010Xb
5Xh	0101	0 Z ² 1	Z ² Z ² Z ²	0101001Xb 0101010Xb 0101011Xb
9Xh	1001	0 Z ² 1	1 1 1	1001100Xb 1001101Xb 1001110Xb

NOTES:

1. Upper address bits are decoded in conjunction with the select pins.
2. A tri-state or "Z" state on this pin is achieved by leaving this pin unconnected.

Note: System management software must be aware of the processor dependent addresses for the thermal sensor.

Table 57. Memory Device SMBus Addressing

Address (Hex)	Upper Address ¹	Device Select			R/W
	bits 7-4	SM_EP_A2 bit 3	SM_EP_A1 bit 2	SM_EP_A0 bit 1	bit 0
A0h/A1h	1010	0	0	0	X
A2h/A3h	1010	0	0	1	X
A4h/A5h	1010	0	1	0	X
A6h/A7h	1010	0	1	1	X
A8h/A9h	1010	1	0	0	X
AAh/ABh	1010	1	0	1	X
ACH/ADh	1010	1	1	0	X
Aeh/AFh	1010	1	1	1	X

NOTES:

1. . This addressing scheme will support up to 8 processors on a single SMBus.

8.0 Boxed Processor Specifications

8.1 Introduction

The Intel® Xeon™ processor with 512 KB L2 cache is also offered as an Intel boxed processor. Intel boxed processors are intended for system integrators who build systems from components available through distribution channels. The boxed processor is supplied with an unattached passive heatsink. It also contains an optional active duct solution, called Processor Wind Tunnel (PWT), to provide adequate airflow across the heatsink. If the chassis or baseboard used contains an alternate cooling solution that has been thermally validated, the PWT may be discarded. This chapter documents baseboard and platform requirements for the cooling solution that is supplied with the boxed processor. This chapter is particularly important for OEM's that manufacture baseboards and chassis for integrators. Figure 43 and Figure 44 show a mechanical representation of a boxed processor heatsink.

Note: Drawings in this section reflect only the specifications on the Intel boxed processor product. These dimensions should not be used as a generic keep-out zone for all cooling solutions. It is the system designer's responsibility to consider their proprietary cooling solution when designing to the required keep-out zone on their system platform and chassis.

Figure 43. Mechanical Representation of the Boxed Processor Passive Heatsink for 3 GHz processors

Figure 44. Mechanical Representation of the Boxed Processor Passive Heatsink for 2 - 2.80 GHz processors

8.2 Mechanical Specifications

This section documents the mechanical specifications of the boxed processor passive heatsink and the PWT.

Proper clearance is required around the heatsink to ensure proper installation of the processor and unimpeded airflow for proper cooling.

8.2.1 Heatsink Dimensions

The boxed processor is shipped with an unattached passive heatsink. Clearance is required around the heatsink to ensure unimpeded airflow for proper cooling. The physical space requirements and dimensions for the boxed Intel® Xeon™ processor with 512KB L2 cache assembled heatsink are shown in [Figure 47](#) (Multiple Views). The airflow requirements for the boxed processor heatsink must also be taken into consideration when designing new baseboards and chassis. The airflow requirements are detailed in the Thermal Specifications, [Section 8.4](#).

8.2.2 Heatsink Weight

The boxed processor heatsink weighs no more than 450 grams. See [Chapter 4.0](#) and [Chapter 6.0](#) of this document along with the *Intel® Xeon™ Processor Family Thermal Design Guidelines* for details on the processor weight and heatsink requirements.

8.2.3 Retention Mechanism and Heatsink Supports

The boxed processor requires processor retention solution to secure the processor, the baseboard, and the chassis. The retention solution contains one retention mechanisms and two retention clips per processor. The boxed processor ships with retention mechanism, cooling solution retention clips, and direct chassis attach screws. Baseboards and chassis designed for use by system integrators should include holes that are in proper alignment with each other to support the boxed processor. Refer to the Server System Infrastructure Specification (SSI-EEB) at <http://www.ssiforum.org> for details on the hole locations. Please refer to the “Boxed integration notes” at <http://support.intel.com/support/processors/xeon> for retention mechanism installation instructions. Please reference [Figure 45](#) for the dimensions of the retention mechanism that ships with the boxed processor. Please reference [Figure 46](#) for a representation of the retention mechanism clip. Retention mechanism clips must interface with the boxed processor retention mechanism area shown in Detail A in [Figure 45](#).

Figure 45. Retention Mechanism

Figure 46. Boxed Processor Clip

Figure 47. Multiple View Space Requirements for the Boxed Processor

8.2.4 Processor Wind Tunnel

The boxed processor ships with an active duct cooling solution called the Processor Wind Tunnel, or PWT. This is an optional cooling solution that is designed to meet the thermal requirements of a diverse combination of baseboards and chassis. It ships with the processor in order to reduce the burden on the chassis manufacture to provide adequate airflow across the processor heatsink. Manufacturers may elect to use their own cooling solution.

Note: Although Intel will be testing a select number of baseboard and chassis combinations for thermal compliance, this is in no way a comprehensive test. It is ultimately the system integrator's responsibility to test that their solution meets all of the requirements specified in this document. The PWT is meant to assist in processor cooling, but additional cooling techniques may be required in order to ensure that the entire system meets the thermal requirements.

See [Figure 49](#) and [Figure 50](#) for the Processor Wind Tunnel dimensions.

8.2.5 Fan

The Processor Wind Tunnel includes a 25mm fan for use with processors ≤ 2.8 GHz, or a 38mm fan for use with processors running at 3 GHz. The 38mm fan provides the high performance required to meet the demanding thermal requirements of processors running at 3 GHz. The 38mm fan provides local fan speed control. There is a temperature diode on the fan that measures the inlet temperature to the fan and adjusts the speed accordingly. The benefit is that system manufacturers can pass acoustical requirements while still being able to pass thermal requirements at maximum ambient temperature

8.2.6 Fan Power Supply

The Processor Wind Tunnel includes a fan, which requires a constant +12V power supply. A fan power cable is shipped with the boxed processor to draw power from a power header on the baseboard. The power cable connector and pinouts are shown in [Figure 48](#) and the fan cable connector requirements are detailed in [Table 58](#). Platforms must provide a matched power header to support the boxed processor. [Table 59](#) contains specifications for the input and output signals at the fan heatsink connector. The fan heatsink outputs a SENSE signal, an open-collector output, that pulses at a rate of two pulses per fan revolution. A baseboard pull-up resistor provides V_{OH} to match the baseboard-mounted fan speed monitor requirements, if applicable. Use of the SENSE signal is optional. If the SENSE signal is not used, pin 3 of the connector should be tied to GND.

The power header on the baseboard must be positioned to allow the fan heatsink power cable to reach it. The power header identification and location should be documented in the platform documentation, or on the baseboard itself. The baseboard power header should be positioned within 7 inches from the centre of the processor socket

Figure 48. Fan Connector Electrical Pin Sequence

Table 58. Fan Cable Connector Requirements

Item	Specification
Connector Type	- Fan connector must be a straight square pin, 3-pin terminal housing with polarizing ribs and friction locking ramp. - Match with a straight pin, friction lock header on the mainboard. - Manufacturer and part number or equivalent: - AMP[†]: Fan connector: 643815-3, header: 640456-3 - Walden[†] / Molex[†]: Fan connector: 22-01-3037, header: 22-23-2031
Pin Out (See Figure Above)	- Pin 1: Ground; black wire. - Pin 2: Power, +12 V; yellow wire. - Pin 3: Signal, Open collector tachometer output signal requirement: 2 pulses per revolution; green wire.
Fan cable length (Drawing 747887):	The fan cable connector must reach a mating mainboard connector at any point within a radius of 110 mm (4.33") measured from the central datum planes of the enabled assembly (datum planes A, B & C on Drawing AXXXXX).
Fan cable routing	Fan power cable must be routed in such a way to prevent it from contacting the fan impellor and it must be positioned in a consistent location from unit to unit.

Table 59. Fan Power and Signal Specifications

Description	Min	Typ	Max	Unit	Notes
+12V: 12 Vot Fan Power Supply	6.0	12.0	13.2	V	
IC: Fan Current Draw			1.5,400	A,mA	
SENSE Frequency		2		Pulses per fan revolution	1

NOTE:

- Baseboard should pull this pin up to V_{CC} with a resistor.
- 1.5A is required for 3 GHz and 400 mA is required for frequencies 1.80 GHz and 2.80 GHz.

Figure 49. Processor Wind Tunnel General Dimensions

Figure 50. Processor Wind Tunnel Detailed Dimensions

8.3 1U Rack Mount Server Solution

The 1U solution contains a passive heatsink and a foam pad, in addition to the retention solution included with the other options. Because of the small form factor, the 1U heatsink is not as efficient at dissipating heat as the general-purpose heatsink. In order to ensure maximum thermal efficiency, the foam pad must be attached to the top of the 1U heatsink, blocking airflow between the heatsink and the chassis cover. This will force air through the heatsink fins instead of allowing it to bypass over the top. See [Figure 51](#) and [Figure 52](#) for more detail on installation.

Figure 51. Exploded View of the 1U Thermal Solution

Figure 52. Assembled View of the 1U Thermal Solution

8.4 Thermal Specifications

This section describes the cooling requirements of the heatsink solution utilized by the boxed processor.

8.4.1 Boxed Processor Cooling Requirements

The boxed processor will be directly cooled with a passive heatsink. For the passive heatsink to effectively cool the boxed processor, it is critical that sufficient, unimpeded, cool air flow over the heatsink of every processor in the system. Meeting the processor's temperature specification is a function of the thermal design of the entire system, and ultimately the responsibility of the system integrator. The processor temperature specification is found in [Chapter 6.0](#). It is important that system integrators perform thermal tests to verify that the boxed processor is kept below its maximum temperature specification in a specific baseboard and chassis.

At an absolute minimum, the boxed processor heatsink will require 500 Linear Feet per Minute (LFM) of cool air flowing over the heatsink. The airflow must be directed from the outside of the chassis directly over the processor heatsinks in a direction passing from one retention mechanism to the other. It also should flow from the front to the back of the chassis. Directing air over the passive heatsink of the boxed Product Name processor can be done with auxiliary chassis fans, fan ducts, or other techniques.

It is also recommended that the ambient air temperature outside of the chassis be kept at or below 35 °C. The air passing directly over the processor heatsink should not be preheated by other system components (such as another processor), and should be kept at or below 45 °C. Again, meeting the processor's temperature specification is the responsibility of the system integrator. The processor temperature specification is found in [Chapter 6.0](#).

9.0 Debug Tools Specifications

The Debug Port design information has been moved. This includes all information necessary to develop a Debug Port on this platform, including electrical specifications, mechanical requirements, and all In-Target Probe (ITP) signal layout guidelines. Please reference the *ITP700 Debug Port Design Guide* for the design of your platform.

9.1 Logic Analyzer Interface (LAI)

Intel® is working with two logic analyzer vendors to provide logic analyzer interfaces (LAIs) for use in debugging systems. Tektronix* and Agilent* should be contacted to get specific information about their logic analyzer interfaces. The following information is general in nature. Specific information must be obtained from the logic analyzer vendor.

Due to the complexity of systems, the LAI is critical in providing the ability to probe and capture front side bus signals. There are two sets of considerations to keep in mind when designing a system that can make use of an LAI: mechanical and electrical.

9.1.1 Mechanical Considerations

The LAI is installed between the processor socket and the processor. The LAI pins plug into the socket, while the processor pins plug into a socket on the LAI. Cabling that is part of the LAI egresses the system to allow an electrical connection between the processor and a logic analyzer. The maximum volume occupied by the LAI, known as the keepout volume, as well as the cable egress restrictions, should be obtained from the logic analyzer vendor. System designers must make sure that the keepout volume remains unobstructed inside the system. Note that it is possible that the keepout volume reserved for the LAI may differ from the space normally occupied by the processor heatsink. If this is the case, the logic analyzer vendor will provide a cooling solution as part of the LAI.

9.1.2 Electrical Considerations

The LAI will also affect the electrical performance of the front side bus; therefore, it is critical to obtain electrical load models from each of the logic analyzers to be able to run system level simulations to prove that their tool will work in the system. Contact the logic analyzer vendor for electrical specifications and load models for the LAI solution they provide.

Intel® Xeon™ Processor with 512 KB L2 Cache
