

### DESCRIPTION

The MP3336 is a compact, dual-channel, high-power, flash, LED driver that can drive up to 2A in flash mode for each LED. It is usually applied for camera phones to improve image and video quality in low-light environments. The MP3336 operates with a selectable 1/2/3/4MHz switching frequency and uses a synchronous, current-mode PWM boost converter to regulate the LED current with two high-current sources. The MP3336 provides high efficiency and an optimized solution for smaller PCB spaces.

The MP3336 features a standard I<sup>2</sup>C interface, dual LED channels, rich protection modes, and high power density and performances. The MP3336 can also support flash, assist, torch, indicator, and 5V DC modes.

The cathodes of the dual-flash LED are referenced to GND, which is better for improving thermal performance in layout. The MP3336 is available in a WLCSP-20 (1.6mmx2.0mm) package.

### FEATURES

- 2.7V~5.5V Input Voltage
- 1/2/3/4MHz Selectable Max Switching Frequency
- Switching Frequency Fold-back Function
- 400kHz I<sup>2</sup>C Compatible Interface
- Standby/Flash/Assist/Torch/Indicator/5V DC Modes

#### **Flash Mode**

- Up to 2A/Ch Programmable Current with  $\pm 7\%$  Accuracy for Each LED, 7.84mA/Step

#### **Assist/Torch Mode**

- Up to 319mA/Ch Programmable Current with  $\pm 7\%$  Accuracy for Each LED, 1.25mA/Step

#### **Indicator Mode**

- Works in 31.5kHz PWM Dimming Mode with 2/16, 3/16, 4/16, 5/16 Duty Cycle
- Used for Blinking and 128/256/512ms Selectable Blinking Time

#### **5V DC Mode**

- Output Constant 5V DC Voltage
- 1A to 4.2A Programmable Input DC Current Limit Protection
- External Torch/Strobe/TX Pin
- LED Forward-Voltage Balance to Improve Efficiency
- VIN to VOUT Disconnection Function
- Low-Battery Voltage Protection
- LED Short/Open Protection
- VOUT-GND Short Protection
- Over-Voltage Protection (OVP)
- Over-Temperature Protection (OTP)
- Input Under-Voltage Lockout (UVLO) Protection
- Available in a WLCSP-20 (1.6mmx2.0mm) Package

### APPLICATIONS

- Smartphone Flash LED Application
- Cameras for Tablets
- Digital Still Camera

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are registered trademarks of Monolithic Power Systems, Inc.

## TYPICAL APPLICATION

## ORDERING INFORMATION

| Part Number* | Package                | Top Marking |
|--------------|------------------------|-------------|
| MP3336GC     | WLCSP-20 (1.6mmx2.0mm) | See Below   |

\* For Tape & Reel, add suffix -Z (e.g. MP3336GC-Z)

|----------------------------|---------------|---------------|
| WLCSP-20 (1.6mmx2.0mm) ... | 55 ...        | 0.5 .. °C/W   |

### NOTES:

- 1) Exceeding these ratings may damage the device.
- 2) The maximum allowable power dissipation is a function of the maximum junction temperature  $T_J$  (MAX), the junction-to-ambient thermal resistance  $\theta_{JA}$ , and the ambient temperature  $T_A$ . The maximum allowable continuous power dissipation at any ambient temperature is calculated by  $P_D$  (MAX) =  $(T_J$  (MAX) -  $T_A$ ) /  $\theta_{JA}$ . Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- 3) The device is not guaranteed to function outside of its operating conditions.
- 4) Measured on JESD51-7, 4-layer PCB.

# ELECTRICAL CHARACTERISTICS

V<sub>IN</sub> = 3.6V, T<sub>A</sub> = 25°C, unless otherwise noted.

## BLOCK DIAGRAM

**Figure 1: Functional Block Diagram**

## OPERATION

The MP3336 is a dual-channel, LED driver with I<sup>2</sup>C interface that supports image capture for camera flash. The MP3336 can work in flash mode, assist mode, torch mode, indicator mode, and fixed 5V DC output mode. Table 1 shows how to set these operation modes.

### LED Driver Operation

The MP3336 is a synchronous, current-mode, PWM, boost converter that can work with 1/2/3/4MHz. The MP3336 regulates the boost loop by detecting and controlling the headroom voltage across the current source (V<sub>OUT</sub>-V<sub>LED1/2</sub>).

When the device is enabled by LED\_EN, the synchronous PMOS works with a 250mA current source first to charge the output capacitor until V<sub>OUT</sub> rises above 2.3V. The device changes to boost switching mode if the voltage across the current source is less than the target reference, which is set by V<sub>TH\_PAS</sub>. If V<sub>IN</sub> is very close to V<sub>OUT</sub>, the IC switches to boost switching mode and pass mode automatically to minimize power loss. In pass mode, the synchronous PMOS is fully turned on. During the current start-up, the current ramps up step-by-step smoothly until the target setting current is reached.

**Table 1: Operation Mode Setting**

| Configuration |      |                    |           |         |        |         | Mode      |
|---------------|------|--------------------|-----------|---------|--------|---------|-----------|
| TX            | TOR  | STR <sup>(6)</sup> | LED1/2_EN | STR_MOD | 5V_MOD | LED_MOD |           |
| X             | High | Float              | 1         | X       | X      | 00      | Torch     |
| X             | X    | Float              | 1         | X       | X      | 10      | Assist    |
| X             | X    | X                  | 1         | X       | X      | 01      | Indicator |
| 0             | X    | High               | 1         | 1       | X      | 11      | Flash     |
| 1             | X    | High               | 1         | 1       | X      | 11      | Flash     |
| X             | X    | X                  | 1         | 0       | X      | 11      | Flash     |
| X             | X    | X                  | X         | X       | 1      | X       | 5V        |

**NOTE:**

6) STR is high active when STR\_POL = 1. STR is low active when STR\_POL = 0. Table 1 is based on STR\_POL = 1.

### Standby Mode

By default, if V<sub>IN</sub> is higher than UVLO and EN is pulled high, the device enters standby mode. In this mode, only the I<sup>2</sup>C is active and ready to communicate with the host.

### Torch Mode

In standby mode, if TOR goes from low to high, the device changes to torch mode and the current ramps up step-by-step to the target current after setting the LED1/2\_EN bits to 1. The target current for the LED can be set through registers I1\_TOR and I2\_TOR. The ramp-up slew rate can be set by the register TUP\_I. The current can be disabled by pulling TOR to low or by setting the LED1/2\_EN bits to 0. These two bits control the two LED current sources respectively. By pulling TOR low, the LED1/2\_EN and LED\_MOD bits reset to the default automatically if LED\_SD is 0 (see Figure 2).

**Figure 2: Torch Mode**

### Assist Mode

To enter assist mode, set the LED\_MOD register to 10 and LED1/2\_EN to 1. The current ramps up to the target value, which is set by I1\_TOR and I2\_TOR. The ramp-up slew rate can be set by register TUP\_I. The current can be disabled by switching to standby mode or by

setting the LED1/2\_EN bits to 0. These two bits control the two LED current sources respectively (see Figure 3).

Figure 3: Assist Mode

### Indicator Mode

When LED\_MOD is set to 01 and LED\_EN1/2 is set to 1, the MP3336 enters indicator mode, which provides a low-current output (see Figure 4). In this mode, the driver current sources work in a 31.5kHz PWM dimming mode. The current amplitude can be set by I1\_TOR and I2\_TOR, while the indicator current step ramps up more quickly at a rate of 7.84mA/step, compared to torch mode's ramp-up rate of 1.25mA/step. The final amplitude in this mode can be calculated with Equation (1):

$$7.84\text{mA} \times I1/2\_TOR \quad (1)$$

The duty cycle is set by the INDI\_PWM register. When disabled, switch to standby mode or set the LED1\_EN and LED2\_EN bits to 0.

Figure 4: Indicator Mode

In indicator mode, the MP3336 can also work in blinking mode. If blinking is enabled, the IC

works in indicator mode during the blinking time, and the LED current source is disabled during the blinking time (see Figure 5). The blinking time is set by the TBK0-1 bits in register 0FH.

Figure 5: Blinking Time

### Flash Mode

The device can work in flash mode in three ways: hardware and level trigger mode, hardware and edge trigger mode, and software and edge trigger mode. All of the below description are based on bit STR\_POL = 1. The default high level is active for STR. When STR\_POL is set to 0, STR is low active.

#### 1. Hardware and Level Trigger Mode

In this mode, STR\_MOD = 1, STR\_LV = 1, LED1/2\_EN = 1, LED\_MOD = 11. The flash current begins to ramp up after STR goes high. The current is set by I1\_FL and I2\_FL, and the ramp-up time is set by TUP\_I. The flash current ends when STR is pulled low or when the flash timer ends. After flash, LED\_MOD is reset to standby mode, and LED1/2\_EN is set to 0 if LED\_SD = 0. If LED\_SD = 1, LED\_MOD and LED1/2\_EN are not reset. The LED1 and LED2 current sources are controlled by the LED1\_EN and LED2\_EN bits respectively. If the STR is pulled low before the flash timer ends, the flash current shuts down at the STR falling edge (see Figure 6). Conversely, if the flash timer set by FL\_TIM ends before STR goes low, the flash current terminates immediately. The time-out indicator bit FT\_TO is set to 1 and is not cleared until it is read back or the input power resets (see Figure 7).

Figure 6: Hardware and Level Trigger Flash Mode without Time-Out

Figure 7: Hardware and Level Trigger Flash Mode with Time-Out

## 2. Hardware and Edge Trigger Mode

In this mode, STR\_MOD = 1, STR\_LV = 0, LED1/2\_EN = 1, and LED\_MOD = 11. The flash current begins to ramp up after STR goes high. The current is set by I1\_FL and I2\_FL, and the ramp-up time is set by TUP\_I. The flash current ends when the flash timer set by FL\_TIM ends. After the flash, the LED\_MOD is reset to standby mode, and LED1/2\_EN is set to 0 if LED\_SD = 0. If LED\_SD = 1, the mode and LED\_MOD and LED1/2\_EN are not reset. The

LED1 and LED2 current sources are controlled by the LED1\_EN and LED2\_EN bits respectively (see Figure 8).

Figure 8: Hardware and Edge Trigger Flash Mode

## 3. Software and Edge Trigger Mode

In this mode, without STR, STR\_MOD = 0, LED1/2\_EN = 1, and LED\_MOD = 11. The current is set by I1\_FL and I2\_FL, and the ramp-up time is set by TUP\_I. The flash current ends when the flash timer set by FL\_TIM ends. After the flash, the LED\_MOD is reset to standby mode if LED1/2\_EN is set to 0 with LED\_SD = 0. If LED\_SD = 1, the LED\_MOD is not reset if ILED1/2\_EN is set to 0. The LED1 and LED2 current sources are controlled by the LED1\_EN and LED2\_EN bits respectively (see Figure 9).

**Figure 9: Software and Edge Trigger Flash Mode**

### Torch Mode to Flash Mode

The MP3336 can switch to flash mode from torch mode directly when STR goes from low to high if STR\_MOD = 1. After flash, the operation functions the same way as in flash mode (see Figure 10).

**Figure 10: Torch Mode to Flash Mode**

### Assist Mode to Flash Mode

During assist light mode, the device can switch to flash mode from assist mode directly when STR goes from low to high if STR\_MOD = 1. After flash, the operation functions the same way as in flash mode (see Figure 11).

**Figure 11: Assist Mode to Flash Mode**

### 5V DC Output Mode

If 5V\_MOD is set to 1, the device can work in a fixed 5V output mode, and the control loop is taken over by the voltage loop (see Figure 12). The LED current sources can still output a current if the mode conditions are met as described above. Care must be taken to ensure that the thermal condition is normal, since 5V directly powers the LED. It is recommend to set LED1/2\_EN to 0 during 5V mode.

**Figure 12: 5V DC Mode**

### Maximum Switching Frequency Setting

The maximum switching frequency can be selected by the SW\_FS bits when working in boost mode. 1 /2 /3 /4MHz can be selected to optimize efficiency.

## Switching Frequency Fold-back

When the max switching frequency is set to 2/3/4MHz in switching mode, if the voltage across the current source is larger than the value set by the register bits VTH\_PAS, the IC switches to 1MHz to improve efficiency and EMI. With 1MHz, if the voltage across the current source is still larger than the value set by the register bits VTH\_PAS, the IC can stretch the frequency down until it reaches about 100kHz with FS\_SD = 0. If the LED load becomes lighter and the input voltage increases further, the IC switches to pass mode from 100kHz. With FS\_SD = 1, the IC switches directly to pass mode from 1MHz.

## Load Balancing

To improve efficiency, the device provides load balancing to prevent unbalanced forward voltage drops between the dual LEDs (see Figure 13). To enable this function, the bit BAL\_ON must be set to 1. Supposing  $V_{LED1} > V_{LED2} + V_{LED\_HYS}$ , the LED1 current drops step by step while the LED2 current rises step by step. Finally,  $|V_{LED1} - V_{LED2}| < V_{LED\_HYS}$  or  $I_{LED1} < 90\%I_{LED2}$ .

However, the maximum adjustment range of each LED current is limited to 10%. Because of the limitation, if there is a large difference between  $V_{LED1}$  and  $V_{LED2}$ , the load balance function cannot make  $|V_{LED1} - V_{LED2}|$  drop below  $V_{LED\_HYS}$ , but it is still helpful to further reduce the voltage difference and improve efficiency.

Conversely, if  $V_{LED2} > V_{LED1} + V_{LED\_HYS}$ , the operation is the same.

**Figure 13: Load Balancing**

## LED Output Current Reduction

When the MP3336 works in flash mode, output current reduction may occur due to the following three conditions:

### 1. TX is High

During flash mode, if TX goes from low to high, the flash current drops to the current set by I\_TX in under 5μs and sets the FT\_TX bit to 1. If TX goes low, the current ramps up to the flash current again (see Figure 14).

**Figure 14: Flash Mode with TX Pulse**

### 2. Input DC Current Limit is Triggered

If the input DC current limit set by IL\_DC register is not sufficient, a current reduction may occur. The actual current in the IFL\_ACT register can be read back during flash.

#### Input DC Current Limit Protection

The MP3336 uses the input DC current limit protection to avoid drawing too much current from the battery. This current limit can be programmed by the IL\_DC register from 1A to 4.2A with 250mA/step when IL\_DC < 3A and with 300mA/step when IL\_DC > 3A. If the input current hits the input current limit threshold, the LED output current stops and holds until the input current limit drops below the current limit threshold. The fault bit FT\_IDC is set to 1 if the input current limit is triggered. The fault bit remains until it is read back or the input power is reset. The input current limit protection is useful in boost mode because it senses the current of the low-side MOSFET.

### 3. Low Battery Voltage Threshold Is Triggered

During flash pulse, if the battery voltage drops below the threshold set by VBL\_RUN, the current reduces step by step until the battery voltage rises up to the set low battery voltage threshold. The actual current in the IFL\_ACT register can read back during flash and the minimum current caused by the current reduction in IFL\_MIN can be read back after flash.

#### Low Battery Voltage Protection

The device provides low battery voltage protection in flash mode in the following ways:

1. Before flash, if VBL\_SD = 1, and the input voltage is lower than the threshold set by VBL\_RUN, the device remains disabled and sets the fault bit FT\_VBATL to 1. If VBL\_SD = 0, the device ramps to the current set by I\_TX and sets the fault bit FT\_VBATL to 1. The fault bit is cleared after it is read back or when the input power resets.
2. During flash start-up, if the input voltage is lower than the threshold set by VBL\_RUN, the current stops ramping. The fault bit FT\_VBATL is set. During flash pulse, if the input voltage is lower than the threshold set by VBL\_RUN, the current ramps down step by step. The fault bit is set until it is read back or when the input power resets.

After flash, the minimum current caused by the current reduction can be read back through the IFL\_MIN register. The IFL\_MIN value holds until the next flash occurs or until the power resets. The actual current can be read back through IFL\_ACT during flash. This function is useful for determining how much flash current can be drawn from the battery (see Figure 15).

Figure 15: Pre-Flash under Low Battery

#### NTC Detection

If the register NTC\_WD is set to enable NTC detection, the NTC sources a constant 35μA current. If the voltage across the NTC resistor drops below the threshold set by NTC\_WD, the internal fault bit FT\_LEDHOT is set to 1 and the modes are reset to standby mode if LEDT\_SD = 1. If LEDT\_SD = 0, the mode setting is not reset after the fault bit is set. The fault bit remains until it is read back or the power resets. It is recommended to float NTC if this function is not being used.

Figure 16: NTC Detection

#### VOUT-GND Short Protection

If VOUT < 1V, the device stops switching and disconnects the synchronous PMOS to prevent a large current from being drawn from the battery. Set the FT\_VOOSC bit to 1 and reset the mode setting. The fault bit remains until it is read back or the power resets.

#### LED1/2-GND Short Protection

If LED1 < 1V and ILED1 > 5mA, or LED2 < 1V and ILED2 > 5mA, the IC marks off the current source and sets the fault bit FT\_LEDSC but continues switching. If both current sources are marked off, the device stops switching and the mode setting is reset. The fault bit FT\_LEDSC is 1 until it is read back or the power resets. If LED\_EN1 is set to 0, the feedback of the current source 1 is not involved

in the loop control, and fault detections on this channel are also disabled.

### LED1/2 Open Protection

If  $V_{OUT} - V_{LED1/2} < 110\text{mV}$  and  $V_{OUT} > 5.5\text{V}$ , the IC marks off the fault current source and sets the fault bit FT\_OVP but continues switching. If both current sources are marked off, the device stops switching and the mode setting is reset. The fault bit FT\_OVP is 1 until it is read back or the power resets. If LED\_EN1 is set to 0, the feedback of the current source 1 is not involved in loop control, and fault detection on this channel is also disabled.

### Output Over-Voltage Protection (OVP)

If  $V_{OUT} > 5.5\text{V}$ , the device stops switching and resumes normal condition until  $V_{OUT}$  drops below 5.2V. The fault bit FT\_OVP is 1 until it is read back or the power resets.

### Junction Over-Temperature Protection

If LED\_OTAD = 1, the flash current drops to the current set by I\_TX when  $T_J > 130^\circ\text{C}$ . The fault bit FT\_OTP is set to 1. If  $T_J > 150^\circ\text{C}$ , the device stops switching and resets LED\_MOD and LED\_EN1/2. The fault bit FT\_OTP must be cleared to 0 by a read-back or a power reset.

### Time-Out Protection

If the device works in one of the flash modes—hardware and level trigger mode—time-out protection may be triggered. When the STR input pulse is longer than the flash timer set by FL\_TIM, the device is disabled once the timer ends. The device stops switching and resets the mode setting, and the fault bit is 1 until it is read back or the power is reset before restarting.

### Under-Voltage Lockout (UVLO) Protection

If VIN drops below the UVLO threshold, the device stops and all of the registers are reset to default.

## I<sup>2</sup>C Interface Register Description

### I<sup>2</sup>C Chip Address

After the start condition, the I<sup>2</sup>C-compatible master sends a seven-bit address followed by an eighth read (Read: 1) or write (Write: 0) bit. The following bit indicates the register address to or from which the data is written or read. The I<sup>2</sup>C address of the MP3336 is 0x27.

## APPLICATION INFORMATION

### Selecting the Input Capacitor

The input capacitor reduces the surge current drawn from the input supply and the switching noise from the device. The input capacitor impedance at the switching frequency should be less than the input source impedance to prevent the high-frequency switching current from passing through to the input. Ceramic capacitors with X5R or X7R dielectrics are recommended for their low ESR and small temperature coefficients. A capacitor with a higher value can help reduce input voltage ripple and noise. For most applications, a 10µF ceramic capacitor is sufficient.

### Selecting the Inductor

The converter requires an inductor to supply a higher output voltage while being driven by the input voltage. An inductor with a larger value results in less ripple current, a lower peak inductor current, and reduced stress on the internal N-channel MOSFET, but also has a larger physical size, higher series resistance, and lower saturation current.

Choose an inductor that does not saturate under the worst-case load conditions. Select the minimum inductor value to ensure that the boost converter works in continuous conduction mode with high efficiency and good EMI performance. Calculate the required inductance value using Equation (2) and Equation (3):

$$L \geq \frac{\eta \times V_{OUT} \times D \times (1-D)^2}{2 \times f_{SW} \times I_{LOAD}} \quad (2)$$

$$D = 1 - \frac{V_{IN}}{V_{OUT}} \quad (3)$$

Where  $V_{IN}$  and  $V_{OUT}$  are the input and output voltages,  $f_{SW}$  is the switching frequency,  $I_{LOAD}$  is the LED load current, and  $\eta$  is the efficiency.

The switching current is used for peak-current mode control. To avoid hitting the current limit, the worst-case inductor peak current should be less than 80% of the current-limit  $I_{LIM}$ . For most applications, 0.47µH~2µH inductor is sufficient.

### Selecting the Output Capacitor

The output capacitor keeps the output voltage ripple small and ensures feedback loop stability. The output capacitor impedance must be low at the switching frequency. Ceramic capacitors with X7R dielectrics are recommended for their low ESR characteristics. Ensure that the ceramic capacitance is dependent on the voltage rating. The DC bias voltage and the value can lose as much as 50% of their capacitance at the rated voltage rating. Ensure that enough of a voltage rating margin is left when selecting the component. A capacitance that is too low can cause loop instability. For most applications, a 10µF ceramic capacitor is sufficient.

### PCB Layout Guidelines

Efficient PBC layout is critical for stable operation. For best results, follow the guidelines below.

1. Place a ceramic capacitor close to VIN.
2. Use a wider copper wire for input, output, and GND to improve thermal performance.
3. Put as many vias close to GND at the output and input capacitors as possible to improve thermal performance.
